India.—The principal source in India is the Yenangyaung field in Burma, about 272 m. N. of Rangoon on Yenangyaung creek. Other important districts are the Singu, Minbu, Pakokku and Upper Chindwin. The oil is in rocks of Miocene age and is about 30° Baumé (0.8750 sp.gr.). Deep drilling was a feature of the development in this field after 1914. Some wells come in with a large initial flow but fall off rapidly as the territory has been intensively developed. Coal-bearing rocks of Eocene age have yielded oil in small quantities in Assam and in the Punjab. India's production in 1920 was 7,500,000 bar.; in 1919, 8,735,000; in 1908, 5,047,038.

Japan and Formosa.—Japan's principal oil production is found in the Echigo Province field. Since 1908 the most important development has been in Akita prefecture. The first gusher was drilled in this field in May 1914, flowing at the rate of 12,000 bar. daily. Many other large wells have been developed. The Akita gushers have declined rapidly. Oil is obtained from coarse sandstone layers, interstratified with sandy shale of Tertiary age. The oil is about 25° Baumé (0.9032 sp.gr.). A small production is also obtained in Formosa. Production of Japan and Formosa in 1920 was 2,139,777 bar.; in 1919, 2,175,000; and in 1908, 2,070,145.

China.—A joint investigation of petroleum resources in the provinces of Shen-si and Chih-li was undertaken in 1914 by the Chinese Government and a private corporation. Drilling of six wells began in the Yen-chang field, Shen-si, where previously a number of primitive wells had been put down and a small production obtained. In 1916 the abandonment of the enterprise was announced. No oil in commercial quantity was struck.

OCEANIA AND THE EAST INDIES

Dutch East Indies.—Production of petroleum in the Dutch East Indies has shown a steadily increasing tendency. Production is obtained in Sumatra, Borneo and Java. Most of the oil-bearing rocks are associated with beds of coal and lignite of Miocene age. Oil of the Langkat district of Sumatra has a gravity of 33° to 35° Baumé (0.8589 to 0.7692 sp.gr.). Java oil is heavier, ranging between 23° and 40° Baumé (0.9150 to 0.8235 sp.gr.). Borneo oils from shallow wells have a gravity of about 14° Baumé (0.9722 sp.gr.), and from the deeper wells a gravity of from 27° to 33° Baumé (0.8917 to 0.8589 sp.gr.). Production of the Dutch East Indies, including a small production from British Borneo, totalled 17,529,210 bar. in 1920; 15,428,000 in 1919; and 11,041,852 in 1908.

Papua.—Test drilling has been undertaken in Papua, and, while oil has been struck, difficulty has been caused by mud clogging.

Philippine Islands.—Prospecting and drilling work started in the Philippine Is. in 1920 in the Bondoc Peninsula district.

New Zealand and Australia.—Extensive prospecting and drilling work have been done in New Zealand, especially in the vicinity of New Plymouth; South Australia, in the Robe district, and in Queensland, in the Roma district. Exploitation in these districts has failed to develop petroleum production in commercial quantity. New South Wales has developed an oil-shale production amounting in 1918 to 32,395 long tons.

Oil in the World War.—Petroleum was a major essential in industrial, military and naval operations in connexion with the World War. Industrial plants required abnormally large quantities of lubricating oils and fuel oils. There was a rapid expansion in oil-burning fleets, and a new demand on petroleum was made by air craft, by the introduction of petrol-burning motor launches, by tanks used in military operations, and by the creation of the motor transport, which became a chief factor of a mobile army. Petroleum was a contraband of war, and German submarine warfare was largely directed against petroleum tank steamers. Military operations in Galicia and also in Rumania were dictated to a considerable degree by the condition of petroleum supply in the Central Powers. Galicia changed hands several times during the war, and after Rumania's entrance into the war in Sept. 1916 the oil fields of that country fell into the hands of the Austro-German armies. Considerable damage to the Galician and Rumanian fields was caused by military operations, and the output of these countries was reduced during the war. Before the capture of the Rumanian fields a systematic destruction of wells, derricks and oil supplies had been undertaken by an Allied military mission, and the Germans immediately installed a military commandant with trained assistants to rehabilitate the fields. The operations of Turkey against Russia had the Baku oil fields as their objective, and the early British operations in Mesopotamia were chiefly intended as a precautionary measure for the protection of the Persian oil fields.

In all the warring countries special Governmental departments were organized to handle petroleum problems, and in almost every country drastic restriction of home consumption was enforced. In England the Mineral Oil Production Department had jurisdiction over all questions of production of oil from home sources. The Pool Board attended to the distribution of oil in the British Is., and the Petrol Control Department acted on matters of petrol economy. The Petroleum Executive was formed in Aug. 1917 to handle matters of general policy. In France jurisdiction of petroleum matters was placed in the hands of a Commissioner-General of Petroleum, and a Petroleum Importing Consortium was created. During the last year of the war a Government commission for petroleum was formed in Italy, and throughout the war restrictions were placed on the importation and sale throughout that country. In Germany and Austria price and distribution were under control somewhat similar to that of food, and strict rationing was adopted. After the United States entered the war in 1917 a voluntary organization of the American industry was effected under the name of the National Petroleum War Service Committee, and in 1918 the Oil Division of the Government Fuel Administration was established. Restrictions on home consumption in the United States were confined entirely to voluntary methods. The Inter-Allied Petroleum Council, consisting of representatives of Great Britain, the United States, France and Italy, was formed in 1917. This Council arranged for the requirements of each of the Allies and for the transportation of the petroleum allotted.

America supplied 80% of the Allied petroleum requirements. The problem of transporting these great quantities was only secondary to the problem of production. Large additions were made to tanker fleets, principally of Great Britain and the United States, but as there was an inadequate supply of tankers early in the war, and as the German submarines sank many, this feature of the transportation problem was particularly serious. It became necessary to use the double bottoms of cargo vessels for transporting oil, and it is estimated that from 1917 to the close of the war 1,100,000 tons of fuel oil were so transported. The total quantity of fuel oil brought to British bases during the war exceeded 10,000,000 tons, of which 9,100,000 tons were issued to the British Admiralty. In addition American naval tankers imported 560,000 tons, which were distributed by small British craft to U.S. naval units along the British coast. The tanker-building programme, projected by the British Admiralty in the early stages of the war, resulted in the addition of 52 cargo tankers of 380,000 tons' capacity and 49 fleet auxiliaries of 95,000 tons' capacity. In 1918 there were 2,628,961 tons of fuel oil alone shipped from the eastern seaboard of the United States for the use of the Allied navies. In the same year more than 1,000,000 tons of distillates and other petroleum products also crossed the Atlantic, entailing more than 500 tank steamer loadings. The figures made public after the war showed that 48% of the British fleet was depending on oil for fuel. The maintenance of the blockade round the Central Powers involved the steady consumption of petroleum products. In the patrol around the British Is. the steaming of the fleet and other vessels averaged not less than 7,000,000 m. a month. At one time the situation as regards tank steamers was so serious that a single day's delay in any of the vessels caused considerable anxiety. In May 1917 stocks of oil were so low because of heavy shipping losses, due to submarines, that the fleet was unable to exercise properly and the army was frequently on a hand-to-mouth basis. At that date total stocks of oil in Great Britain amounted to only 900,000 tons, and the absolute minimum of safety was considered 1,500,000 tons. After 17 months stocks had been increased to 1,800,000 tons, and on cessation of hostilities the stock was considered satisfactory.

A campaign of intensive development in the petroleum fields, particularly of the United States and Mexico, brought about large increases in petroleum production, but requirements were so great that despite this increase stocks had to be drawn on heavily. At the close of the war American tankers afloat had increased 635,507 gross tons, and 51% of the total gross tonnage of tankers in

service between America, Great Britain, France and Italy was American owned, while 49% was British owned. Because of the increased tonnage at the close of the war the United States was exporting each month for war purposes 2,200,000 bar. of fuel oil, 750,000 of motor gasoline, 500,000 of kerosene and 175,000 of aviation naphtha. The country's exports of fuel oil to Great Britain, France and Italy in 1918 represented an increase of 200% over 1914 and 23% over 1917. At the beginning of 1917 the total requirements of petroleum products for all British services reached a figure of about 3,500,000 tons per annum, nearly double pre-war requirements. By the end of 1918 the figure had increased to nearly 5,500,000 tons per annum. It is estimated that the maximum requirements of the Allies if the war had continued would have occurred in the spring of 1919, when 12,000,000 tons per annum (of which some 8,000,000 tons would have been absorbed by Great Britain) would have been required. During the last 18 months of the war the Inter-Allied Council dealt with between 12,000,000 and 13,000,000 tons of oil.

The British army in France used about 23,000 tons of motor spirit a month during the greater part of the war. The French army's monthly consumption of gasoline was 35,000 tons, of which 30,000 tons came from the United States. In Dec. 1917 the Allies had a scant month's supply of gasoline on hand, and between Dec. 25 1917 and Jan. 31 1918 90,000 tons of petroleum products were shipped to France from the United States, making possible the shifting of troops into threatened areas by motor lorries. Oil stocks in France, before the large shipments early in 1918, had gone down to 25,000 tons, less than the average held in France in normal times. During the days of most active fighting consumption reached as much as 2,000 tons a day. The British Ministry of Shipping was mainly responsible for the transporting of overseas supplies, and the Tanker Division of the Emergency Fleet Corps, U.S. Shipping Board, and a section of the War Trade Board had jurisdiction of the allocation of cargoes and of shipping belonging to the United States. The difficulties of getting production were accentuated by various specifications which each Government required as regards its oil supplies, and steps were taken by the Inter-Allied Council to effect some degree of standardization. In the United States the Committee of Standardization of Petroleum Specifications was formed to standardize petroleum products, requirements of the various Government departments, and also to recommend adoption by the states of standard specifications.

The war opened the eyes of all countries to the value of petroleum products. The Allied countries and the Central Powers conducted extensive investigations to provide substitutes. In Great Britain the Alcohol Motor Fuel Committee was formed to consider the fields of production of alcohol fuel, and its utilization either alone or in conjunction with fuels such as petrol and benzol. Efforts were successfully made to extract crude oil from canal coal on a commercial scale at certain large gas works. The use of coal-tar oils as fuel oil was also considerably increased. Alcohol substitutes for petroleum were extensively experimented with in Germany and in the United States. In the latter country important experiments were made with colloidal fuel. The actual work of petroleum development in the British Is. was undertaken as a war measure, and, as already stated, the drilling of wells was started in Derbyshire, Staffordshire and the Midlothian district of Scotland on behalf of the British Government. Another war achievement was the construction of an 8-in. pipe line, 35 m. long, across Scotland from the vicinity of Glasgow to Grangemouth on the Firth of Forth. This pipe line was built so that tank steamers could discharge fuel oil for the Allied navies at Old Kilpatrick, near Glasgow. The pipe line then conveyed the oil to the Firth of Forth, where it was required by the navies. Tanker transportation to the Firth of Forth was very dangerous. The work of building the stations and ditching for the line was conducted by the British Admiralty, and the line laid by a U.S. naval unit. It was completed shortly before the Armistice was signed. The war also probably hastened the building and completion of the British navy's great oil reservoir at Rosyth. This was con-

structed of reinforced concrete, and is capable of storing 60,000,000 imp. gal. of liquid fuel. Concrete work on the first section began in July 1916, was completed in Aug. 1918, and oil was run into the tanks in Sept. 1918. Construction of the second section began in Aug. 1917, and was completed early in 1919.

Certain important producing and potentially productive oil areas changed nationality as a result of the World War, including parts of Galicia, formerly in the Austro-Hungarian Empire, now a part of Poland; Alsace, now French; Mesopotamia and Palestine, lost by Turkey, and placed under British mandate.

Financial and Industrial Progress.—The expansion of petroleum activity has involved a great increase in financial requirements. While the tendency has been toward consolidation and the perfecting of organizations of great size, there has also been, particularly in the United States, an extraordinary springing up and expansion of companies embracing one or two branches of the business, or often operating in almost every branch. The chief petroleum companies own or lease oil-bearing properties, work their own production, have pipe-line affiliations, own and operate refineries, own and lease tank cars and other marketing equipment, and own and operate tank steamers.

The nationalization of oil-bearing lands—the retention or vesting of ownership of subsoil rights in the hands of the State—has been a pronounced tendency in certain countries. In Russia petroleum lands were nationalized and were operated in part of 1919 and in 1920 by the Soviet Government. Argentina's petroleum development has been almost entirely in the hands of the Government since its inception. In May 1917 a new Mexican constitution provided for the nationalization of petroleum, and various decrees have been promulgated attempting to carry out the nationalization principle. In other Latin-American countries nationalization of petroleum lands is generally adhered to in working out new petroleum codes. Direct Government interest in petroleum development was brought about in Great Britain by the action of the British Government in becoming a majority shareholder in an oil company developing the Persian fields and active in other countries.

The importance of petroleum with respect to national security and industrial prosperity became generally recognized during the World War and resulted in intense investment and speculative interest in oil companies. Statistics compiled for 250 representative American oil companies showed capital invested as of Dec. 31 1919 to be \$2,501,939,914. Of this group 142 companies were organized after 1912. The 108 companies in existence prior to 1912 showed a capital investment of \$717,008,563 on Dec. 31 1911. The compilation showed that of the total increase in capitalization between 1912 and 1919, amounting to \$1,784,841,351, \$707,004,521 was added in one year, 1919. New oil companies formed in the United States in 1917, 1918, 1919 and 1920 represented an amazing capitalization. The records show that in 1920 1,712 companies were organized with an authorized capitalization of \$2,787,000,000; in 1919, 1,629 companies with \$3,786,000,000 capital; 1918, 820 companies with \$1,430,000,000 capital; and in 1917, 512 companies with \$840,000,000 capital.

Capital-borrowing by oil companies in the United Kingdom in 1919 totalled £15,852,600; in 1920 £13,004,600. The total capital of oil and kindred companies registered in the United Kingdom during 1920 was £33,105,050.

Four companies in Germany, classified under the head of "Petroleum, Mineral Oil, etc.," increased their capital in 1920 101,850,000 marks. There was a boom in the oil business in Rumania in 1919 and 1920. In the former year 128 new companies were organized with a total capitalization of 449,000,000 lei (nominal value 94d. or \$.19, but at that time much depreciated). Up to Oct. 1920 168 companies had been organized with an issued capital of 1,640,206,900 lei.

Well-drilling and Field Improvements.—Production is maintained and increased only by the constant drilling of new wells. A territory becomes "proven" after it has been demonstrated by test wells and by active development to have petroleum deposits. The search for oil in unproven territory is generally termed "wildcatting." The wildcatter is sometimes a small operator but more often in recent years a large company, for the operation entails large expenditure.

In the United States, which in 1920 supplied 65% of the world's production, it is generally estimated that from 25% to 40% of current output is "flush" production; that is, production from the large initial flow of new wells, which subsequently would decline to moderate "settled" production or become exhausted. There were about 35,000 new wells completed in the United States in 1920; 24,000 of them were rated as oil producers. At the end of that year there were 7,200 wells drilling and 2,100 rigs erected or building for drilling. The number of wells producing oil in the United States, Oct. 31 1920, was 258,600. The average per well was 4.9 barrels.

The principal drilling systems are: (1) percussion, which includes the standard cable tool (American system) and the pole tool (Canadian system); (2) hydraulic rotary system; (3) combination system; (4) hydraulic circulating system (see 21.319). In the Appalachian region of the United States wells are sunk by the standard or churn system, with a modified light rig, and range in depth from a few hundred feet to 3,000 or 4,000 feet. In many sections groups of wells are pumped from the central station. The yield of wells in the Appalachian field is small, the average for Pennsylvania being about 0.3 bar. per well; New York, 0.2 bar.; Kentucky, 3.1 bar.; W. Virginia, 1.1 bar.; and eastern Ohio, 0.8 barrels. Wells in the mid-continent field are generally drilled by standard tools. The cable system is used in central Texas, and the rotary system in northern Texas and in some districts of Oklahoma. The rotary system exclusively is used in northern Louisiana. The depth ranges from 200 ft. to 3,500 ft., drilling in recent years averaging more than 2,000 ft. Recoveries per acre from mid-continent pools have been generally higher than in the eastern fields, but less than in the Gulf coast and California. The average production per well in Oklahoma and Kansas is 6 bar.; northern Texas, 31.6 bar.; central Texas, 22.9 bar.; and northern Louisiana, 31.6 barrels. The rotary method is used exclusively in the Gulf coast field, the depth of wells ranging from 1,000 to 3,500 ft., and the production per well being 34.6 bar. in coastal Louisiana and 49.7 bar. in coastal Texas. In the Rocky Mountain field the standard and rotary systems are used, the shallow districts of this field also being largely drilled by the standard cable system with the portable rig. The depth of the wells ranges from 1,000 to 3,500 feet. The average production per well is 55.9 barrels. In California drilling is about evenly divided between the standard and rotary systems. The combination rig is also extensively used, and there is some drilling by the hydraulic circulating system. Well-depths range from 1,000 to 3,500 ft. and the average production per well is about 32.3 barrels. A well of average depth in the mid-continent field could be drilled and equipped for less than \$13,000 in 1913. In 1915 the cost increased to about \$14,000; in 1918 to \$24,000; and in 1920 to about \$32,000. A factor in the advance in cost was the increased depth of the average well. Drilling cost of an average well in central Texas in 1920 was \$44,000 to \$68,000; in certain Gulf coast pools, \$39,000; while in the Rocky Mountain and California fields it has risen above \$100,000 per well.

In Mexico, where the wells usually have a great initial production and where the yield of individual wells is often restricted only because of inadequate marketing facilities or as a precaution against water inroads, the percentage of current production that might be termed "flush" is much higher than in any other producing country. Mexico's production is obtained from comparatively few wells. The country's production was credited on Jan. 31 1921 with 367 producing wells, but it is estimated that the bulk of the 1920 production of 163,000,000 bar. was obtained from about 200 wells. The wells average about 2,000 ft. in depth. In the Tehuantepec field the wells have been of shallow depth and short-lived. Drilling in Mexico is about evenly divided between the rotary and standard cable system, and the hydraulic circulating system is used to some extent.

The Canadian pole tool system is used in Canada, while the deeper drilling in the Calgary district has been done by the standard cable system and there has also been some rotary drilling. Wells in the Petrolia district, Ontario, are about 500 ft. in depth and yield from 5 to 25 bar. a month. The standard cable system is principally used in Venezuela, although there has been a good deal of drilling with the rotary method, and a combination of both. Wells in the Mene Grande fields range from 600 to 1,700 feet. Wells in Colombia have been drilled by the cable system and combination cable and rotary, the depth being 1,700 to 2,300 feet. In Peru most wells in the Zorritos field are between 600 and 2,000 ft. in depth; in Labitos from 2,000 to over 3,000 ft.; and in Negritos the average is about 2,500 feet. The standard cable system of drilling is generally used in Peru, but there has been some rotary drilling in the Zorritos field, where a total of 920 wells had been drilled up to 1919, the greatest number of producing wells at any one time being about 50. In Lobitos a total of 118 wells were producing in 1919; in Negritos 732 were active. Drilling in Argentina has been done by practically all methods, but the one in most general use is the Galician pole tool system, which is a modification of the Canadian pole tool system, the equipment providing for a larger and heavier rig. The American standard cable system is also in use in Argentina and there is some rotary and also hydraulic circulating drilling. Production in 1920 was obtained from about 72 wells. In Trinidad wells range from 1,740 ft. in depth. Rotary drilling is used almost exclusively.

The Russian free fall system, a modification of the Canadian pole tool system, is used in Russia. In this, there is a free fall of the tools,

which are then picked up. The diameter of some of the Russian wells is unusually large, the starting diameter being in many cases 36-40 inches. In the Baku field the depth of the wells ranges from 2,000 to 2,500 feet. Baku wells are famous for their large initial flow and large total yield. In Galicia, as well as in Rumania, the Canadian pole tool system, modified and adapted, is generally used, but the hydraulic circulating system is also used. Galician fields require deep drilling, many wells in Boryslaw-Tustanowice being over 4,000 feet. The pole tool system is also extensively used in Rumania. Wells range from 1,000 to 2,500 ft. in depth, and in the Moreni district wells of great capacity have been brought in. The standard cable system with portable rig is used almost exclusively in Italy. The same system, without portable rig, is used in Persia, India and Egypt. The Galician pole tool system is used in the Dutch East Indies. Persian production is obtained at from 1,100 to 1,400 feet. Deeper drilling was resorted to in the Yenangyaung field of Burma with good results, previous drilling not having exceeded 300 or 500 feet. Wells more than 2,000 ft. deep are drilled in the Singu field of India. Wells in Japan range from 600 to 2,000 ft., and the rotary system, introduced in the Akita field in 1913, is used almost exclusively. The diamond drill, a "core" drill used in prospecting for coal, iron and copper deposits, has been introduced as a geological aid in oil-field work. Another means recently employed for drilling test holes and shallow wells is a combination rotary, core and churn drill. Petroleum development of recent years has entailed deeper drilling with consequent heavier demand on oil-field materials. In the United States and in other countries the shallow fields have become exhausted. Drilling to 2,500 and 4,000 ft. has demanded sturdier equipment, heavier and larger casing and improved designs in drilling machinery. Better methods of handling heavy wrenches and bits and of dressing bits have been adopted.

New mechanical devices to aid in well-drilling are constantly being introduced. In electrical rotary drilling, an electric device keeps a check on the drilling crews, indicating when and how long the rotary was shut down. A register giving the weight of pipe resting on the bit is being perfected by experimental tests. It is designed to enable the driller to determine the amount of speed to use in certain formations, with a view to lessening "twist-offs" and thereby lessening the number of fishing jobs. While derricks in most oil-producing countries are chiefly of timber, the all-steel derrick has appeared in certain fields of the United States, Rumania, Galicia, Trinidad, England and South America. Electric power has become a factor in field work and has been adopted for the pumping of wells and for drilling, for driving slush, water, oil and vacuum pumps and for air compressors, gas extractors, machine shops, field lighting and dehydration of oil. Electric power has made advances in Texas, in California and in the mid-continent fields. It has been adopted in Rumania and in the Balakhany-Saboontchy-Romany-Surakhany area and the Bibi-Eibat field of Russia. Electrification of the Yenangyaung field of Burma has also been undertaken. The use of compressed air to increase oil extraction has been introduced recently in certain producing areas. The process consists of pumping compressed air or gas into some wells while others are pumped for oil. The advent of the internal-combustion engine has brought about the extended use of belt, chain and gear driven pumps, while previously single or duplex driven reciprocating steam pumps were mainly used. The turbine pump has also developed oil-field possibilities.

TRANSPORT AND STORAGE

Pipe Lines.—With its large crude-oil production obtained from fields often far from refining and consuming centres, the petroleum industry of the United States has developed pipe-line systems of great mileage and capacity (see 21.320). In the fields themselves there are networks of gathering lines connecting the wells with main trunk lines and railways, the trunk-line systems connecting the fields with the refining centres. It is estimated that pipe lines in the United States totalled about 35,000 miles. Practically all of the crude oil produced (1,300,000 bar. daily) is transported by pipe line, some of it only a few miles and some of it as far as 1,700 miles. About 150,000 bar. a day are taken from the eastern and mid-continent fields to the Atlantic seaboard through a connecting system of pipe lines. Mid-continent crude is also piped to the Gulf coast. It is estimated that the total U.S. production moves by pipe line an average of more than 500 miles. Pipe lines in Mexico have been constructed from the Panuco and Topila fields to Tampico and from the southern fields to Tampico and directly from the southern fields to the Gulf coast, where sea loading lines are installed. There is an international trunk line running into Canada connecting with lines in Ohio. In Venezuela the production in the Mene Grande field is run by pipe line about 35 m. to a refinery at San Lorenzo where there is also a terminal from which crude oil is barged to a refinery on the I. of Curacao. A pipe line of about 25 m. has been constructed from wells in the Colorado district of Colombia to a refinery at Barranca Bermeja on the Magdalena river. The Lobitos field in Peru is connected by pipe line to the port of Talara, 16 m. distant, where there is a refinery and a terminal for export shipping. Argentina has short field pipe lines. In Trinidad there are pipe lines from the Pitch Lake district to refineries at La Brea and Port Fortin and also from this field and the Tabaguite district to Claxton's Bay, where they extend into sea loading lines. Pipe lines

run from the Galician fields to refineries located in and near the fields. Rumania's pipe-line system leads from the fields to refineries near and around Ploesti. A few days before Rumania's declaration of war a Government-owned pipe line was completed from Baicai to Constantza on the Black Sea. Oil from the Balakhany-Saboontchy-Romany-Surakhany oil field is piped to refineries on the outskirts of Baku. Oil from the Bibi-Eibat field is barged to the same place. A kerosene pipe line from Baku to Batoum on the Black Sea was completed in 1905. Grosny oil is piped to refineries near the town of Grosny. The Ural-Caspian fields are connected by pipe lines with Bolshaya Rakushka, where refineries are located. Tcheleken oil is shipped to Baku refineries. Oil from the Maikop field is piped to Ekaterinodar and to the port of Tonapse on the Black Sea.

Oil from the Gemah and Hurghada fields of Egypt is transported by pipe lines to a refinery at Sucz. Pipe lines connect the Maidan-i-Naphtun field of Persia to a refinery at tidewater located at Abadan. Oil from Singu and Yenangyang fields is piped to refineries near Rangoon, a distance of about 275 miles. Oil from the Langkat district of Sumatra is piped to refineries at Pangkalan on the Bay of Aroe. Southern Sumatra fields are connected by pipe lines to refineries at Pladjoe and Bagoe Koenig, both near Palembang. Java production is transported to refineries at Wonokrono and Tjepoe. Borneo oil by lighters to a refinery on the harbour of Balikpapan.

Pump Stations.—In the United States, pump stations are usually 30 to 40 m. apart in the eastern and middle states, but there are cases of long-continued operation of 120 m. with one pump station. A steam pump station usually consists of a pump house, boiler house, gate house, office and tanks. Diesel engines are being installed extensively in pumping stations.

Sea Loading Lines.—Sea loading lines have been installed and are operating in Mexico, Peru, Trinidad, Russia and other places. These lines make possible the loading of vessels several miles at sea and are usually installed where no deep-water harbours exist and where, because of the shallow water, the building of piers would entail prohibitive expenditure. The lines are submarine and are usually coupled ashore, stretched out on rails and drawn into the water by vessels. When it is impossible to couple the pipe ashore, this is usually done on barges or rafts and the line deposited as the work proceeds. The first sea loading line in Mexico was pulled in 1913 by the use of wooden dollies on a wooden track. At present numerous companies have sea lines along the strip of island beach between the Panuco and Tuxpam rivers.

Storage.—Crude-oil storage facilities, where steel tanks or reservoirs, are grouped together on what are generally known as tank farms, some of which in the United States have a capacity in excess of 24,000,000 barrels. Steel tanks are usually of 37,000 or 55,000 bar. capacity, placed about 500 ft. apart from centre to centre. Each tank is surrounded by a levee of sufficient height to hold the entire content of the tank and enclosed for the purpose of isolating fires. Crude oil is stored in steel tanks, concrete tanks and earthen reservoirs, while many of the lease tanks are wooden. There were held in the United States in pipe line and tank farm storage, at the end of 1920, 138,000,000 bar. of crude oil. In addition, 21,000,000 bar. of crude oil were stored at refineries. Tanks are installed at refineries for holding oil during the running at the plants and for storage preparatory to shipment to markets. Stocks of refined products held at U.S. refineries at the close of 1920 totalled 2,433,700,000 gallons. Investigation and experimentation are constantly directed to the reduction of evaporation losses of crude oil and refined products during storage. An investigation by the U.S. Bureau of Mines showed that in just one stage of handling of crude production in the mid-continent field, the volume of gasoline lost by evaporation equaled one-thirtieth of the total gasoline production of the United States. The loss occurred during a few days when oil was stored on leases before being taken by pipe line, and amounted in 1919 in the mid-continent field alone to 122,100,000 gallons. Insulated storage tanks of about 10,000 bar. capacity are being experimented with by a few mid-continent casing-head gasoline manufacturers.

Tanks are usually protected from fire by steam lines from the boiler house so that free steam can be turned into the tanks on the approach of a thunderstorm. This steam displaces the explosive mixture in the tanks. The water spray method is also used. At pipe-line stations, and tank farms and refineries where there is a large number of tanks, a fire protective system which utilizes a frothy or foam mixture is often installed. This mixture has as its ingredients water, aluminium sulphate (crystal), sulphuric acid, ground glue, glucose, sodium bicarbonate and arsenious oxide. The system entails a piping and pumping system and the equipment includes solution tanks and foam-mixing boxes. Each storage tank has a mixing box into which pipe lines leading from the solution tanks discharge. The boxes are outside the tanks and the foam is admitted to the tank through a raised hatchway. The substance spreads over the surface of the oil. To insure the foam reaching the surface of the blazing oil at whatever depth without the bubbles being destroyed by the impact of the drop, a series of baffles is used retarding the descent. Tanks covered with a jacket of asbestos supported by steel framework are being experimented with. Submarine storage tanks, which if required can be rested on sea bottom, have been devised.

Tank Vessels.—The tank vessel plays a large part in the modern petroleum industry. It is used for transporting crude oil from produc-

ing countries and districts to refining countries and centres and for carrying refined products in bulk to the markets of the world. The world's tonnage of tank vessels (including steam, gas, mail and barge) increased from 1,525,000 gross tons in 1914 to about 4,000,000 tons at the end of 1920, with 1,100,000 tons under construction.

Great advances have been made in tanker construction and the loading and unloading of oil from tank vessels. The typical modern tanker carries 16,000 tons of oil, is equipped with quadruple expansion engines and boilers fired with liquid fuel, has a complete shelter deck the whole length of the vessel, oil-tight hatches and two pump rooms with pumps capable of discharging 1,200 to 1,500 tons per hour. The Diesel engine is also used for propulsion in some tankers, while the oil-fired steam-driven turbine is gaining headway. Oil cargoes are now loaded and discharged in a few hours. Devices have been perfected enabling vessels to take on a supply of fuel oil from tankers while under way on the high seas.

REFINING

Refinery Operations.—The rapid expansion of the internal-combustion engine which, as developed in motor vehicles, began to be of importance as a consuming agency of petroleum products in 1907, has elevated gasoline (petrol) to the ranking by-product of crude oil. More recently the conversion of coal-burning vessels and industrial plants to the use of oil and the extension of utilization of the Diesel engine (an internal-combustion engine which does not demand so volatile an oil as gasoline) in the marine and in the industrial fields has placed fuel oil in a position of great prominence. Even so great an increase in crude-oil production as was recorded between 1908 and 1920 could not have supplied these consuming agencies had not refining methods been improved, new processes developed, and refinery capacity greatly expanded. As in the case of crude-oil production, the greatest refinery expansion has been in the United States, where in 1915 it is estimated there were 302 refineries with a crude-oil capacity of 1,043,245 bar. daily. On Jan. 1 1921 there were 415 refineries with a daily capacity of 1,888,800 barrels. The types of plants represented in this total were: 35 complete, 302 skimming, 60 wax and lubricants, 7 asphalt and 11 topping.

United States refineries in 1920 ran 434,000,000 bar. of crude oil, and produced 4,882,000,000 gal. of gasoline; 2,320,000,000 gal. of kerosene; 8,861,000,000 gal. of gas oil and fuel oil; 1,047,000,000 gal. of lubricating oil; 541,000,000 lb. of wax; 576,000 tons of coke; 1,290,000 tons of asphalt; and 1,492,000,000 gal. of miscellaneous oil. The principal refining centres in the United States are in the mid-continent territory, in the Pennsylvania region, and along the Atlantic, Gulf and Pacific coasts. Every large producing area has developed a refining industry, while the seaboard plants, in most instances, owe their location to strategic advantages respecting large domestic and export markets. Mexico has built up a substantial refining industry, although the largest proportion of its crude-oil production is transported to the United States for topping and refining, in most part by Atlantic and Gulf coast plants. Most of the Mexican plants are topping plants (that is, they divide the crude into tops, distillates and gas and fuel oils), but there are a few more complete refineries. All the refineries are located along or adjacent to the Gulf of Mexico or the eastern seaboard, comparatively near the producing fields. In 1920 there were 12 refineries reported in operation in Mexico with a daily capacity of 19,600 cub. metres of refined products. Four of these refineries were classified as complete plants, six as topping plants and two as natural-gas gasoline plants. There were five plants under construction, two complete refineries, one a topping plant and one a natural-gas gasoline plant. In 1920 61,000,000 bar. of Mexican crude oil were run by U.S. refineries. Canada has developed a substantial refining industry, these refineries operating on Canadian, United States, Mexican and Peruvian crude oil. There are one or more refineries or topping plants in Venezuela, the I. of Curaçao, Colombia, Trinidad, Peru and Argentina, these operating on domestic oil or oil from nearby territories. Galician crude oil is handled by refineries located within a radius of about 150 m. from the city of Lemberg, in and near the oil fields, and also by the Continental refineries in Hungary, Austria and Germany. It is estimated that Galician refineries are capable of handling about 40% of the crude production. Rumania's refineries are mainly located in the Prahova district and also in the Bacau, Dambovitza, Constantza and Neamt districts. In 1920 Rumanian refineries used 988,000 tons of petroleum, and produced 212,000 tons of benzene, 197,000 tons of lamp oil, 30,000 tons of lubricants and 473,000 tons of fuel oil. The output of the different refined products by Russian refineries in 1916 (last figures available) totalled 56,917 million poods of fuel oil, 6,926 million poods of lubricating oils, 135 million poods of solar oils, 944 million poods of benzene and 57 million poods of paraffin. Russian refineries are located at Blacktown, suburb of Baku, these running oil from the Baku fields, at Grosny and Bolshaya Rakushka and at Ekaterinodar and Shirvansky. There are local refineries in Egypt, Persia, India, the East Indies and Japan, and Persian oil is also being handled by a refinery at Swansea, Wales.

Continuous Distillation.—Continuous-process stills were first introduced by Norman Henderson, a British chemist, in connexion with the distillation of shale-oil. This system was subsequently adopted by many refiners of petroleum. A modification of Henderson's launches of stills was the addition to each member of

of a fractionating column, endeavouring to carry out the fractionating in one stage so that the one-bench stills would provide finished products. Similar considerations led to the development in California of the Trumble process, introduced by M. J. Trumble, a California chemist, consisting of an elaborate series of heat interchanges. In this process, oil is heated in a tubular furnace. It is dropped down a tower where, by means of distributors, it is brought in contact with the hot side of the column still and so gives a film evaporation. A recent modification of stills is the Allan system, introduced by Hugh Allan, a British chemist, whereby the oil is vaporized in the ordinary kind of Henderson still, but in place of being subsequently redistilled, or being collected via a column, vapours are blown into a series of vertical pipes, getting a fractional condensation from member to member, the latent heat of the high boiling components being used to re-evaporate any condensed volatile oil, thus obtaining the fractions desired. Topping and skimming plants to raise the flash point and to dehydrate heavy oil have multiplied rapidly, particularly in the United States. The skimming industry is represented in all the major oil fields and has other purposes which give the plants practically a universal field in the oil industry, namely, to remove the lighter constituents of the oil for storage for a long period, thus reducing the losses from evaporation, to dehydrate or clean the oil and, in conjunction with a complete refinery, to remove the lighter fractions cheaply and quickly, leaving a residue to be re-run for lubricants, coke and other products.

Cracking Processes.—The commercial development of the cracking process subsequent to 1913 marked an epoch in the petroleum industry. The growing importance of the internal-combustion engine made necessary a higher yield of motor fuel from the limited crude-oil supply, if the demands of this consuming agency were to be met. Modern cracking dates back to the patent obtained in 1889 by the late Sir Boverton Redwood and Prof. Dewar, British chemists (see 21,322), but commercial development followed the first patent of Dr. W. M. Burton, an American chemist, in 1913.

The following classification of oil cracking processes (representative patents) is made by the Kansas City Testing Laboratory (*Bulletin No. 15*):

- I. Cracking in the vapour phase.
 - A. Atmospheric pressure.
 - Oil gas plants, very high temperature.
 - Pintsch gas plants, very high temperature.
 - Blaugas plants, 1,000–1,200° F.
 - Parker (W. M.) process at 1,000° F. with or without steam.
 - Greenstreet Cherry red with steam.
 - B. With increased pressure.
 - Rittman process above 950° F. and 200–300 lb. pressure.
 - W. A. Hall process 1,100° F. and about 75 lb. pressure.
- II. Cracking in the liquid phase.
 - A. With distillation.
 1. At atmospheric pressure.
 - Luther Atwood (1860).
 - McAfee process with aluminium chloride.
 - Russian and American practice for illum. oils.
 2. Above atmospheric pressure.
 - Dewar and Redwood (1889).
 - Bacon and Clark at 100–300 lb.
 - Burton (Standard Oil Co.) 650–850° F. and 60–85 lb.
 - Dubbs, J. A., over 10 lb. and over 300° F.
 3. Very high pressure (over 27 atmospheres).
 - B. Without distillation and with high pressure.
 1. Without vapour space for equilibrium (continuous processes).
 - Benton (1860) 700–1,000° F. and 500 lb.
 - Goebel-Wellman.
 - Mark (English).
 2. With vapour space.
 - (a) Intermittent.
 - Palmer (below 27 atmospheres for aromatics).
 - (b) Continuous.

Dr. Burton's process is now extensively used in the United States. The development of this patent and the large-scale adaptation of the cracking process marked an era in the history of petroleum refining.

The following is a summary of an address made by Dr. Burton in May 1918, on the occasion of the presentation to him of the Wm. Gibbs medal by the American Chemical Society.

Dr. Burton pointed out that in 1910 the demand for gasoline created by automobiles began to grow so rapidly that it was obvious that something would have to be done to increase the supply of naphtha products. In those days the average yields of various products of petroleum were about as follows: naphtha products 18%, kerosene or illuminating products 30%, lubricating products 10%, loss 3%, leaving about 40% which was sold for gas-making or fuel in lieu of coal. The problem was to convert the high-boiling fractions existing in fuel and gas oil into low-boiling fractions needed by the internal-combustion engine. Dr. Burton and his associates worked for almost two years trying to devise a practical method, first by superheating and dissociation at high temperatures, but at atmospheric pressure; and, secondly, by the employment of various re-

agents, but their efforts were not successful. Having tried everything else that suggested itself these engineers decided to attack the problem from the pressure distillation standpoint. In view of the fact that distillation must take place at temperatures ranging from 350°C. to 450°C., at which the tensile strength of steel begins to diminish very rapidly, and in view of the fact that steel at such temperatures, in the presence of carbonaceous matter (and even of free carbon, which often comes as the result of pressure distillation), is likely to absorb such carbon, become crystalline and lose its tensile strength, the practical refiner doubted the success and safety of this method.

The first large still built had a charging capacity of 6,000 gal. of heavy oil. Serious leaks were encountered, but this problem was finally solved, as the oil carbonized under the influence of the high temperature and the carbon deposits stopped the leaks. There were many puzzling problems to be solved, such as the devising of a safety valve that would operate freely in spite of the intense heat and the presence of carbonaceous matter. The entire apparatus had to be constructed in such a way as to insure ease of operation and freedom from excessive repairs. The production and disposition of the so-called "fixed gases" were troublesome. It was found that in some cases the heavy oil with which the operation began evolved more gas than was needed to maintain the desired pressure, whereas other oils evolved an insufficient amount of gas for this purpose. This obstacle was converted into an aid by arranging a large number of stills in parallel so that the superfluous gases from some stills were conducted to others that needed them. The plan gave a perfect method of securing uniform pressure and control.

By starting with fuel-oil products having boiling points ranging from 200° C. to 350° C., it was possible to secure a very substantial yield of a product having boiling points ranging from 50° C. to 200° C., and it was found that losses thus incurred were trifling, averaging less than 3 per cent. It was found that the high-boiling residues thus produced yielded a product almost identical with the natural asphalt.

Developed from the single 6,000 gal. still there were then (1918), Dr. Burton stated, over 500 stills of a larger capacity. During the preceding five years more than 20,000,000 bar. of gasoline or naphtha products had been produced by these stills in the United States.

It is estimated that cracked gasoline probably accounts for about 15% of all gasoline manufactured in the United States. Casing-head gasoline, manufactured from natural gas, the development of which ranks with cracked gasoline as one of the most important refining advances, is perhaps the source of from 12% to 15 per cent.

Natural Gas.—The United States and Canada produce all but a small fraction of the natural gas output of the world (see 21,321). The main areas of Pennsylvania, W. Virginia and Ohio have developed remarkable staying qualities, and these three states produced virtually two-thirds of the total production of the continent. The mid-continent field has shown a great increase in the natural gas production and the Wyoming field has proved productive. There is some natural gas production in Russia, Rumania, Persia, Galicia, India, Japan and Mexico. The total production of natural gas in the United States in 1918 was 721,000,000,000 cubic feet. It is estimated that no less than 14,000,000 inhabitants of the United States are enjoying this fuel as a source of heat, light and power.

Natural Gas Gasoline.—Although the foundation of the natural gas gasoline industry in the United States was laid in 1903 and 1904, the real expansion of this important phase of gasoline production began in 1909. In 1911, the first year for which statistics on the subject are available, 132 plants produced 7,425,839 gal. of raw gasoline from natural gas. In 1918 the industry included 1,004 plants which produced 282,535,550 gal. of raw gasoline. Of the total, 865 were compression plants producing 219,767,207 gal. and 139 absorption plants producing 62,768,343 gallons. A canvass made in 1921 showed a total of 444 casing-head gasoline plants in Kansas, Oklahoma and northern and central Texas, having a daily output of 1,101,155 gal. of raw gasoline. Prior to 1916 the greatest proportion of gasoline production from natural gas was obtained from casing-head gas, oil-well gas or "wet" natural gas by the compression and condensation method. The development of the absorption process has extended the field of the natural gas gasoline industry to include practically all of the natural gas production in the United States, for there is but little gas production that does not contain an appreciable percentage of pentane and hexane, the hydrocarbons of the paraffin series that are the principal constituents of gasoline. Much of the so-called "wet" gas obtained from oil wells when they are first opened and from gas wells that produce no petroleum, has been sufficiently rich in gasoline vapours to warrant treatment by the absorption process, though excluded from successful treatment by compression and condensation. The following extracts are from *Handbook of Casinghead Gas*, by Henry P. Westcott:—

"Casing-head gas received its name from the casing-head on the top of the casing through which it flows. It is the gas that flows from oil wells, coming out between the casing and the tubing. The volume varies from a few hundred cubic feet to several hundred thousand cubic feet per day. Invariably the gas becomes richer in gasoline content as the wells grow older. Generally a gasoline plant or property consists of a number of oil leases grouped around a main compressor station in which the actual making of gasoline takes place. The gas lines from different wells on each lease run to a main line in which is placed a meter to measure the gasoline from that

lease. The main line runs to the compressor station or plant. There are a few plants extracting gasoline from a volume as small as 5,000 cub. ft. of gas per day, while some of the large plants are extracting gasoline from a volume of two and three million cub. ft. per day. The amount of gas necessary to make a profitable proposition is not only dependent upon the volume of gas but also on the quality of the gas. To further assist in the production, a vacuum pump or compressor is installed in the same building with the booster compressor. The object of the vacuum pump is to pump the gas from the wells and create a vacuum which materially increases the flow of the gas. Vacuum has been used in oil wells to increase the production even when gas could not be used for making gasoline.

"There are two processes for extracting gasoline. The one most commonly used is that of compression. The other is the absorption process, which is not only used with casing-head gas but also with natural gas, commonly called "lean gas," which carries as low as one-tenth of a gallon or less of gasoline per one thousand cubic feet. This process is used with gas at high as well as low pressure.

"In the compression process, the equipment consists of one or more two-stage compressors, coils, accumulating tanks, electric generator and other accessories. The casing-head gas is compressed to a pressure of from 50 to 300 pounds and then passed through a system of coils on which cold water is constantly dripping. This cools the gas, condensing the gasoline from it, the liquid being separated into respective accumulating tanks and the residue gas passing off to be used for power or heating purposes. After the gasoline is collected in the accumulating tanks, it passes into blending tanks, where it is blended with naphtha and other blending mediums to lower the gravity so as to permit of shipping without severe loss through evaporation and to make the shipping of it a safe matter.

"The absorption process is a method of passing the gas through oil and separating the gasoline vapour from it by absorption of gasoline into the oil. There are two general designs in absorption plants, one of which uses the horizontal and the other the vertical absorbers. With either system the oil is used over and over again."

Work of experimentation has been done on a process for extracting gasoline from natural gas by a method whereby natural gas is passed through absorbers containing charcoal, the gasoline absorbed by the charcoal and then distilled out.

Marketing of Products.—Expansion of the use of petroleum products has resulted in many improvements in marketing methods and great additions to marketing equipment and facilities. In the United States a large number of tank cars is used in transporting products from refineries to consuming centres and to ports for export shipment. The tank car is still used to some extent to carry crude oil from the field to refineries, but chiefly this is when a new field is opened up and before pipe-line connexions have been made. Tank cars are widely used in Europe for petroleum products.

There were 49,901 petroleum tank cars in the United States and Canada on Jan. 1 1914, and in 1921 the number had increased to 137,493. Rigid requirements are enforced in tank-car construction in the United States. Cars must be of steam boiler quality, and exceptional strength is prescribed for the frame. The insulated tank car to handle highly volatile casing-head gasoline has been successfully introduced and is also being adopted for transporting straight-run gasoline because it reduces loss by evaporation. The growth of motor-vehicle gasoline demand, particularly extensive and rapid in the United States, has created new distributing methods and devices. In that country and Canada gasoline filling installations for motor cars have been established in the cities and on every road of any importance. Thousands of filling stations have been built. Gasoline is delivered from tank wagons or steel barrels to the tanks built underground at the filling stations. The oil is lifted from these tanks by pumps (which measure the amount given by each stroke of the pump) and delivered through a hose into the automobile's tank. Lubricating oil at some stations is delivered in much the same way. An innovation is the visible pump at filling stations.

Fuel-oil bunkering stations have been established along the ocean routes to meet the increase in the oil-burning naval and merchant fleets of all countries. These stations include large storage tanks and berth and loading facilities in some cases, while in many instances they are simply storage reservoirs and oil is loaded on steamers from barges supplied from these stations. It is estimated that the number of fuel-oil stations for steamships located on trading routes approaches 300.

PETROLOGY (see 21.323).—During 1910-21 there was a steady advance in all departments of petrology, and new developments occurred which were not only interesting in themselves but gave promise of being important in the future. Up to a comparatively recent time petrology was in the main a descriptive science. The discovery of the application of the microscope to the study of very thin sections of rocks opened up a new field of investigation and showed how defective had been the means employed by the older geologists. It became possible to identify even the smallest mineral grains and to ascertain their relations to one another and the manner in which they were built together from the rock mass. For many years the description of the microscopic characters of minerals and rocks was held to be, if not the only, at least the most important, part of petrographical literature. The processes by which rocks are altered by atmospheric agencies and by underground water were revealed in detail. A great body of literature was accumulated, and a great diversity of rock types soon came to be recognized, some of them occurring in abundance in many parts of the world and others rare and exceptional either in their mineral composition or in their minute structures. Textbooks of petrography were in general a description of the recognized rock types, their composition, structure and the stages of their decay, with notes on their geographical distribution and their geological age. Chemical analyses were used principally as a means of identifying the classes to which individual rocks belonged and as a guide to the minerals of which the rocks consisted.

In time it came to be recognized that this aspect of the subject, if not unscientific, was at least incomplete. More attention of recent years has been directed to other problems connected with rocks—such especially as the conditions of their origin, their chemical classification and the physical laws which determine what minerals shall be formed, in what order they will crystallize and through what stages they will pass when subjected to cooling, pressure and metamorphism. In fact, the effect of the laws of physics and chemistry on the mineral composition and structure of rocks had become by 1921 a branch of petrology which was rapidly developing. It would be a mistake to regard this as wholly a new development, for many of the older geologists—such as Hall Gregory Watt, Daubrée, Fouqué and Lévy, Sorby, Morozewich—had carefully studied these problems and had made some notable discoveries. Essentially, however, it was necessary to attack these questions by experimental methods. The old charcoal furnace was very unsatisfactory and difficult to regulate; the gas furnace in all respects was much superior; but the advent of the electric furnace has placed in the hands of the experimentalist a weapon of enormously greater power and far more manageable. There is no difficulty now in attaining temperatures such as occur in the deeper parts of the earth's crust and in the interior of volcanoes and in maintaining these temperatures quite steady for several days or weeks if necessary. The electric pyrometer has replaced the gas thermometer and the older Seger and Wedgwood cones, and has reached such precision that an error of one or two degrees is all that need be expected in measuring temperatures up to 1600° Centigrade. By means of the electric arc, temperatures can be obtained which are beyond those which exist in the upper parts of the earth's crust, but furnaces of this type have been little used in these researches. Very high pressures can be easily obtained provided the temperature is low and there is no necessity to study the action of compressed gases. It is less easy, however, to perform experiments by which the action of steam and other gases on molten rock magmas at temperatures about 1000° and under pressures over 100 atmospheres can be exactly determined. More than one investigator has now been able to attain this, and a very correct reproduction of the conditions under which igneous rocks crystallize is consequently possible in the laboratory.

Descriptive petrology has been by no means in abeyance, though the five years of war turned the activities of many geologists to other fields. Exploring expeditions, such as those of Scott, Shackleton and Bruce in the Antarctic, have brought home large collections of rocks which have been examined and described, and the constant activities of geological surveys in all parts of the world, together with the researches of geological specialists, have added largely to our knowledge.

Igneous Magmas.—Of the three great groups into which rocks are naturally subdivided, the sedimentary, igneous and metamorphic, the first is on the whole best understood and presents the smallest number of unsolved difficulties. The manner in which sediments are laid down on the bottoms of seas and lakes, in river deltas and valleys and on land surfaces, at the present time is open to investigation by simple means, and, except in the case of the deposits of the deeper parts of the oceans, is reasonably clear. Igneous magmas, on the other hand, are essentially obscure in their origin and history, and they have been the subject of much investigation in recent years. The origin of magmas is a problem belonging to geology rather than petrology. They have been regarded as unconsolidated remnants of the primeval molten globe, which by geological changes, such as the secular contraction arising from cooling and the pressures by which mountain chains have been upheaved, have been afforded an outlet to the surface, where they appear as volcanoes, or have been forced between the rocks of the upper layers of the earth's crust where they may be laid bare by subsequent denudation as "bosses" of granite or gabbro or intrusive sills of porphyry or dolerite. Others have held that magmas may arise in whole or in part by the fusion of solid rocks (of any of the above three classes); the agencies producing fusion being rise of temperature, either through crushing and movement or by depression into those regions where a high temperature naturally prevails, or through penetration of gases from the earth's interior which are not only intensely hot but are capable of combining and setting free large quantities of energy. It is conceivable also that deep within the earth's crust masses of rock occur at temperatures so high that, if pressure be relieved by the vaulting-up of the overlying crust or by fissures opening to the surface, they may become liquid and rise through any available channels.

Hardly less obscure than the origin of magmas is the question of their variety or differentiation. The outstanding fact in this connexion is that no large developments of igneous rock are really homogeneous and even in small masses it is frequent to find that a great number of varieties or rock-species occur, differing in their chemical composition and their minerals. Granite, diorite, gabbro, norite and peridotite may all occur within a small outcrop not more than one or two square miles in area. The origin of differentiation has been much discussed. Some have ascribed it to diffusion or to a principle by which the heavier atoms in the molten mass will be concentrated either towards the bottom or towards the cooler edges or surfaces of contact with the surrounding rocks. Along these lines no satisfactory explanation has been found. More recent speculations have followed three lines: (a) subsidence or flotation of crystals; (b) absorption of sedimentary or other foreign rocks; (c) concentration of vapours.

(a) *Subsidence or Flotation of Crystals.*—When crystals form in a liquid they will, if heavier than the liquid, tend to subside and be collected near the base; and if lighter, they will tend to rise. If the crystals differ in composition from the liquid, as they usually do, consolidation will result in a mass which is not homogeneous. Thus, for example, olivine crystallizes early in a basic magma and, being heavy, will tend to sink; consequently magnesia and iron will be in excess (and silica will be less abundant) at the base, while felspar will predominate towards the top of such a mass. Instances occur showing this arrangement, but they are very exceptional; it is not the case that dolerite and gabbro masses as a rule have a pale-coloured felspathic top and a dark base rich in olivine and the oxides of iron. For such cases as do occur another explanation is often available. If now it were possible at an advanced stage in crystallization to drain away or force into another position the still liquid part of the magma a type of rock different from the original magma would be produced, because most of the heavy ferromagnesian minerals would have been abstracted.

The explanation is so simple and so well justified by experiment that it is difficult to believe it has no application in the differentiation

of rock types. There is much evidence, however, that forbids us to accept it as important. For example, the study of great dolerite intrusions by means of bores shows that they are generally nearly homogeneous throughout. Top and bottom are very much the same as a rule; yet these masses must have cooled and crystallized with extreme slowness; and every chance was afforded for the accumulation of heavy crystals in their deeper parts. Again, it is the case that where many varieties of rock occur in one mass the densest are not generally in the lowest horizons. Still more important is the fact that field evidence often shows clearly that the more basic members of a complex intrusion have been injected in a liquid state into an earlier less basic mass already in position. In that case, if the more basic member was produced by the gravitational sinking of heavy crystals these must have been subsequently melted up, a process for which it is very difficult to suggest an explanation.

(b) *Absorption of Foreign Rocks.*—A second method of differentiation which has received much attention of recent years is by absorption of country rock. A gabbro mass, for example, may be supposed to dissolve a felspathic sandstone with which it is in contact and thus give rise to a more acid magma which might be represented by quartz-dolerite or even by granite. Intrusive masses of igneous rock, as they ascend from beneath, break across the overlying strata and may shatter them into many small blocks. On these and on the surrounding walls a solvent action is likely to take place. If the invaded rock is heavier than the intrusive magma its fragments will tend to sink, and as they are warmed up they will slowly disappear. There can be no doubt that this action is by no means unusual and many good instances of it are known, but there is little reason to believe that it is an important cause of differentiation. Where igneous rocks have absorbed sediment in any quantity they present in general an abnormal facies. Granites, for example, which have dissolved clay, slate or mica-schist usually contain andalusite, sillimanite, cordierite, garnet or corundum, minerals which do not normally occur in such rocks. The magmas are said to be "contaminated." Gabbros under similar conditions contain cordierite, garnet and an excess of hypersthene (forming cordierite norites) and are easily distinguished from normal gabbros. Absorption of limestone by some nepheline syenites is indicated by the presence of crystalline calcite in the igneous rock, and peridotites may contain corundum. Perhaps the diamond is an accessory of this type in olivine rocks which have dissolved graphitic matter. Even when igneous rocks are absorbed the result will as a rule be an abnormality. This is fairly evident in the majority of cases merely by a study of the analyses of true igneous rock types and ordinary sediments.

It is to be remembered, however, that a study of the crystallized igneous rocks exposed by denudation of the earth's surface reveals to us merely the last stages in their history when the upward propulsive force was spent, the fluid mass had come to rest, its temperature had fallen to such a point that crystallization had begun, part of its gases had escaped and the whole mass was encased in a solid envelope which had resulted from the rapid chilling of its external parts in contact with the cold surrounding rocks. At an earlier stage the magma was at a higher temperature and was in active movement. Constant stirring was going on and dissolved matter rapidly scattered through the whole mass. In the deeper parts of the crust the solid rocks may be mostly gneisses or old intrusive rocks different in character and in their relative abundance from the sediments of post-Archaean times, richer in alkalis and more nearly akin in composition to the igneous masses. These conditions would favour absorption and mask the consequences; and if it took place on a very large scale and time were given for diffusion a magma might be produced which would closely mimic a purely igneous magma. It has also been suggested that the absorption of foreign matter might upset the equilibrium of the original magma and give rise to partial magmas incompletely soluble in one another. It would be very difficult in such a case to determine the original nature of the rock or the amount and composition of the material dissolved.

(c) *Concentration of Vapours.*—The theory that differentiation of magmas arises from the formation of partial magmas during cooling, which separated because they became insoluble in one another (as phenol does with water), is favoured by many geologists, but a recent examination of the physical laws determining the production of such magmas has led to the conclusion that nothing is known that would make this process appear likely. Many geologists, however, who have a wide knowledge of igneous rocks in the field, hold that there is evidence to show that differentiation took place before crystallization began, and that the various types of rock were already distinct when they were injected in liquid form into the positions they now occupy.

It has been suggested, though it has not been clearly explained, that the gases dissolved in magmas determine the sequence of crystallization and may exert a powerful influence in differentiation. A magma rich in gases when it begins to crystallize yields crystals of anhydrous minerals. The gases, if they do not escape, must increase in relative amount in the liquid residuum. The early minerals are those like olivine and augite, which can be crystallized without difficulty from anhydrous melts; the later minerals, such as the alkali feldspars and quartz, crystallize readily only in presence of steam and other gases (or of solvents of a nature not usually present in rocks). In some respects the crystallization of an igneous rock

resembles the cooling and evaporation of a saline solution, the gases playing the part of solvent. The minerals appear in the order of their insolubility. It is probable that the history of magmas will never be clearly understood till a very careful study is made of the consolidation of rock-making silicates under high pressures of steam and other gases such as are known to abound in natural volcanic magmas.

Classification of Magmas.—The igneous rocks of one geological period and province have often so many peculiarities in common that they can be regarded as having resulted from the consolidation of a single reservoir of molten matter. The chain of volcanoes that fringes the shores of the Pacific Ocean from Tierra del Fuego to Alaska, and thence by Japan and the Philippines to Java and Sumatra, is characterized by rocks which have so much similarity in many important characters that they are certainly of allied origin, even if they have not proceeded from the one source. These rocks are all of Tertiary and recent age; their eruptions began in Eocene or Miocene time and have continued, with more or less frequent intermissions, up to the present day. For another example of this we may take the igneous rocks of the western and mid-Atlantic area, from Jan Mayen, through Iceland, the Hebrides, Canaries, Cape Verde Is., etc. All these volcanic centres have many rock types in common, and the whole assemblage is strikingly different from the Pacific igneous rocks. Each of these magmas has been taken as a type, and it has been found that in the older geological periods they are also represented; for example, the early Devonian eruptions in Scotland are distinctly of the Pacific type, while the Carboniferous eruptions in the same district are of the Atlantic type. If we seek for a precise definition of their respective characters it is not easy to give a complete answer. It may be said, however, that the Pacific suite has a great prevalence of hypersthene andesites, and andesites of all kinds. The Atlantic lavas, on the other hand, are predominantly olivine basalts, with trachytes and phonolites. Another feature which is especially striking is that practically all the rocks carrying nepheline and other feldspathoids or "alkali minerals" are found in the Atlantic suites. This has been regarded as proving that the Atlantic magmas are richer in alkalis and the Pacific in lime, but it is by no means certain that this is the explanation. In fact, a full chemical discussion of the relations of these rock-series to one another has yet to be undertaken, but from the work of Becke it seems that the Pacific are essentially richer in silica, and in the "light" elements generally, while the Atlantic contain more of the "heavy" elements, such as magnesia, iron, chromium, titanium. Several authors have pointed out that the rocks of the Pacific group are associated with a folded mountain chain and consequently have appeared in a region undergoing lateral compression and upheaval; the Atlantic, on the other hand, are associated with a region of subsidence, with vertical dislocations along lines of fissure and faulting—in other words, a region subjected to lateral tension and depression. A third group of igneous rocks, very well characterized and distinct in many respects, is the pillow lavas or spilites, which are perhaps the most abundant volcanic rocks of the earlier geological periods and are very widespread in the Lake Superior district, middle Europe, Wales and Scotland. Among these lavas types rich in soda are common and albitization is a frequent pneumatolytic change. These rocks seem to accompany depressions formed in consequence of folding.

The attempt to classify volcanic magmas in groups which accompany definite types of earth movements, folding and faulting, is exceedingly fascinating. A general survey of the world's volcanics from this standpoint has been undertaken by Iddings and Stark, but the results are by no means conclusive. A great deal has yet to be done before we understand the full range of variation of many local magmas, their relation to one another and the approximate age of the intrusive types. It seems, however, that Atlantic, Pacific and spilite suites are not in all cases sharply distinct. Harker believes, for example, that the Hebridean Tertiary magmas of Scotland are Atlantic with some Pacific affinities. He had formerly classified them as Pacific. Bailey and Clough have found in the same district a group of pillow lavas occupying a central volcanic subsidence or "caldera." In that case, accordingly, all three types occur in one narrowly cir-

cumscribed area. If so, they cannot be regarded as distinct types of magma, but rather as facies which may be developed or may appear as offshoots of a magma. Their connexion with definite types of telluric movement becomes doubtful. American petrologists also, from a study of the Tertiary magmas of the Western States, are by no means satisfied that the alkali rocks, such as phonolites, tephrites and leucitic lavas, may not belong to a definitely Pacific assemblage. In Australia, Atlantic and Pacific magmas seem to be intermixed, but in Africa Atlantic igneous rocks accompany fault-fissuring, and this extends into Arabia and Palestine. There is no doubt that on a broad scale the Atlantic and Pacific types have appeared again and again in the earth's history, and have maintained their distinctive characters. The distinction, however, is not absolute, and the rule has many exceptions. Recognition of a number of additional types has recently been proposed, and along this line it is probable that there may be considerable advance in the near future.

Experiments on Constitution of Binary Magmas.—A molten rock magma may be regarded as a liquid composed principally of oxides (mostly silicates). It crystallizes from a variety of causes, of which cooling is the most important, though relief of pressure and escape of gases may also play a part.

The laws followed in such a case have been very carefully investigated, not only for metals, salts and organic compounds but also for many minerals. It is generally true that a mixture of two substances will have a lower consolidation point than one of the pure substances, and, if mixed in certain proportions, they will consolidate at lower temperatures than either of the components. Thus salt and ice, if mixed in the solid state at temperatures a little below the freezing-point of water, will melt, forming a liquid which is colder than the ice originally taken; and aqueous solutions of salts have always a freezing-point lower than that of pure water. For each pair of substances there is a definite mixture which has the lowest temperature of consolidation and this is known as the eutectic mixture.

In the diagram (fig. 1) the horizontal coordinate represents composition, the vertical represents temperature. A mixture of any given composition is represented by a vertical line and different points in that line represent different temperatures of the mixture. The two sloping lines AE and EB divide the diagram into two regions, of which the uppermost indicates substances in a purely liquid state; below the line the substance is in part or wholly in a solid condition. A vertical (composition) line, accordingly, when it

FIG. 1

cuts these lines shows where a substance begins to crystallize. The point where the curves meet is the eutectic point E, and shows the composition of the mixture which has the lowest freezing temperature and the temperature at which it consolidates. The horizontal line drawn through the eutectic point separates the diagram into two regions, a lower one in which the substance is entirely solid and an upper one in which liquid is present. If we take any vertical line in the diagram, it will indicate a mixture of definite composition ST and, followed downwards, it shows the changes taking place in such a mixture as the temperature falls. Above the line AE the mixture is a cooling liquid. At S crystallization begins. At T the last liquid portion disappears and consolidation is complete; below T the substance is a cooling solid. The diagram refers only to substances that crystallize on solidifying; glasses are solids which essentially resemble highly viscous liquids in their properties. When crystallization begins the substance which is in excess of the eutectic mixture will crystallize out first, the residual liquid becoming poorer in that component until it has reached the eutectic composition, when the two components will go on crystallizing simultaneously till all is solid. The composition of the liquid will travel along the line AE from S to the point E, where it will remain constant.

Such a diagram is based on a series of experiments in which a known mixture of two substances (very carefully purified) is heated in a furnace (generally electric) to a temperature well above its melting-point. The mixture is then allowed to cool slowly and steadily, and its temperature recorded at short intervals or continuously by some form of pyrometer or recording thermometer. The rate of cooling can be very accurately ascertained and plotted (fig. 2). Crystallization is attended by liberation of heat (the liquid losing its latent heat as it passes into a solid), and this involves a retardation of cooling. The simple liquid cools at a uniform rate; crystallization

begins and the cooling slows down; at a certain point the liquid is all crystallized and the mixture, now a solid mass of crystals, will go on cooling uniformly. The change of slope in the curve of cooling accordingly corresponds to the passage of the substance from S to E in temperature (or from the purely liquid to the purely solid areas).

The physical condition of the substance at any given temperature can also be ascertained by the method of chilling. If the charge be taken from the furnace and plunged in water (or in some cases mercury) the mixture consolidates almost immediately, and any parts which were liquid will assume the form of a glass, or a very finely crystalline aggregate. This is especially the case with silicates, many of which crystallize with difficulty. Microscopic investigation will enable us to determine the nature and relative proportions of the crystals which were present. The results obtained can be checked by experiments on mixtures having a different composition, and in this way a complete diagram built up on a sound experimental basis. The case outlined above is the simplest known. Many complications may appear, requiring special precautions and elaborate investigation. Thus the liquid may not begin to crystallize at the proper point on the upper curve, as some substances crystallize with difficulty and the liquid becomes "undercooled." A heating-up experiment may be tried to check the cooling experiments; the same phenomena should appear in the reverse order if no complications are present. Many silicates crystallize with great difficulty in ordinary crucible experiments (such as the feldspars, albite and orthoclase). Again, it may be impossible to melt the mixture we desire to investigate in any furnace which is suitable for experiments of this kind. Magnesia, alumina, and lime are examples of substances which cannot be fused at temperatures such as 1600° to 1700° C., which are the limits of accurate work in our laboratories at present; part of the diagram accordingly will be incomplete when substances like these are studied, but an approximate solution can generally be made by extrapolation. Another frequent complication is the appearance of transformations in the solid state. The first mineral to crystallize becomes unstable as the temperature falls and changes spontaneously into another crystalline form of the same substance. The change will be attended by an alteration in the slope of the cooling curve, for in such cases heat is either liberated or absorbed, and successful chilling tests can often be made by which the mineral transformation can be clearly demonstrated. Silica, for example, appears in three minerals, cristobalite, tridymite and quartz, the transition temperatures being 1470° and 870°. Each of these minerals occurs in two forms. Carbonate of lime has a high-temperature and a low-temperature form. Below 1190° calcium metasilicate crystallizes as wollastonite; above that temperature it forms another mineral, pseudo-wollastonite. Many of these "high-temperature" forms are not known as natural minerals, and as a rule they are very rare in rocks, probably because rock cooling is essentially a slow process, and the most stable forms at low temperatures are the only ones likely to be present when the mass has completely cooled. Some very interesting results have been obtained in this field of research; for example, it is known that quartz has two

FIG. 2.

modifications, one above 575°, the other below that temperature, and it has been proposed to use quartz as a geological thermometer to show at what temperature it crystallized in a rock mass. If above 575° it would appear as quartz and on cooling would pass into α-quartz; and by various indications, such as crystalline form, cracks, etc., a record of this transformation may be obtained.

Very interesting investigations of the process of crystallization occur when two or more of the minerals formed are members of an isomorphous series and can in consequence form mixed crystals. This is very common among the minerals of igneous rocks, of which the feldspars, pyroxenes, olivine (and probably also hornblende, mica, nepheline and the feldspathoids) all belong to isomorphous series. If we have, for example, two components such as albite and anorthite, they will tend to form mixed crystals (known generally as plagioclase feldspars). Anorthite has the higher melting-point (about 1550° C.); albite crystallizes in crucibles only with great reluctance at a temperature about 1100° C. A mixture containing equal proportions of anorthite and albite will melt at about 1450°, and on cooling will begin to form crystals at that temperature.

These crystals will contain about 60% anorthite—that is to say, they are enriched in the less fusible component. As crystallization proceeds, the feldspar that separates becomes gradually less rich in anorthite. The composition of the liquid also alters, because the crystallization is abstracting anorthite molecules more rapidly than albite molecules. This process may go on till the feldspar has all crystallized, the last deposited being near albite in composition, and the crystals, examined microscopically, will show zones, of which the internal are rich in anorthite and the external are progressively richer and richer in albite. But if sufficient time is allowed, a reaction sets in between the crystals and the liquid; in other words, the feldspars crystallized are not in equilibrium with the magma except at the moment of crystallization, and as the magma becomes richer in albite it will attack the early plagioclase, replacing it by a variety containing more albite. These phenomena are well known to petrologists as zonal structure of plagioclase feldspars; and corrosion of the cores and internal zones of the crystals is almost universal in such rocks as basalt and andesite. Rocks of similar composition which have cooled very slowly, such as gabbro and norite, as a rule do not contain zoned plagioclase crystals, no doubt because equilibrium has been attained and homogeneous crystals formed by the process above described.

FIG. 3.

This may be illustrated by fig. 3. The horizontal line represents composition, the vertical temperature. A is 100% albite, B is 100% anorthite. The upper curve is the liquidus above which there is only liquid; the lower is the solidus below which all is crystallized: between these lines is a space representing stages in which crystallization is going on but still incomplete. Each point on the solidus has a corresponding point on the liquidus, which is found by drawing a horizontal line across the intervening space. A mixture of any composition, say *a* at *ab*, is completely liquid. As the temperature falls it begins to crystallize at *b*. The crystals formed have the composition *c*. Further cooling results in the formation of crystals at *b'* the composition being *c'*. At *b''* all is crystallized, the last crystals being *d*. If resorption is completely accomplished the final crystals have the composition *x*, but they are usually more rich in albite: this will depend on the rate of cooling, the number and size of the crystals formed, and on a variety of other factors.

The theoretical investigations of Roozeboom and Gibbs have shown that five types of crystallization of isomorphous substances may occur, in some of which the mutual solubility of the two components is unlimited, while in others it is limited so that only mixed crystals of certain types may occur. Several of these have been identified in rock-forming minerals, and others are suspected though not yet proved.

Ternary Magmas.—Magmas of three components (ternary) are much more complicated than binary magmas. To represent their behaviour a triangular diagram is necessary. Usually an equilateral triangle is employed and the distance from any point to the three sides of the triangle is made to represent the three components of any mixture in their true proportions; the sum of these three perpendiculars is constant and equal to the height of the triangle: if lines be drawn through the point, parallel to the sides of the triangle, they will cut the sides at distances which will represent the relative proportions of the components. Any mixture of three components can be represented by one point in this triangle. To represent temperature another coördinate is required which is perpendicular to the plane of the triangular diagram: and a solid model must be made, resembling a triangular prism with flat base and an irregular surface representing the consolidation temperatures as the top of the prism. Each of the three vertical surfaces of the prism represents the behaviour of the mixture of two of the components.

To enable us to construct such a model a very large number of experiments must be made, first with binary mixtures and then with mixtures of the three substances. Their exact temperature of first crystallization must be ascertained in each case and also the nature of the mineral which crystallizes. Simultaneous crystallization of two minerals will follow, and the temperature at which the second mineral appears is to be determined. Three minerals will ultimately

begins and the cooling slows down; at a certain point the liquid is all crystallized and the mixture, now a solid mass of crystals, will go on cooling uniformly. The change of slope in the curve of cooling accordingly corresponds to the passage of the substance from S to E in temperature (or from the purely liquid to the purely solid areas).

the subject has more recently made rapid advances, due largely to the creation of new laboratories and the institution of new chairs devoted to pharmacological research. The chief importance of the work lies in the application of the knowledge gained of the physiological action of drugs to the treatment of disease in man and animals; and, though there have been periods when this branch of therapy—in spite of its antiquity and persistence—has been suspect, recent research leading to new, more accurate, and more scientific use of drugs has placed the subject in a position so indubitable that the time is not in sight when the practice of medicine or surgery will be able to dispense with its services.

The main directions of recent advances in knowledge may be indicated. The action of familiar drugs becomes daily more accurately known, leading to a juster estimate of their value and greater precision in the use of them in disease. New remedies are being introduced and older remedies superseded. The enormous development of synthetic chemistry has furnished many potential remedies, all of which are now subjected to pharmacological investigation before they are used on man. One relatively recent development which has proved fruitful in results of great practical importance in the treatment of disease is that of experimental therapeutics, where the cure of disease artificially produced in experimental animals is investigated. So far this has been most successful in the case of experimental trypanosomiasis, largely owing to the ease with which a disease of this nature can be induced in laboratory animals and the constancy and certainty of its duration.

Here only such developments of pharmacology need be mentioned as have already passed from the by-way of mere academic interest into the highroad of practical application.

Of the simpler saline compounds the familiar Epsom salts—magnesium sulphate—has been found to have more interesting actions than that for which it is generally used. When given as a purgative very little of it is absorbed into the blood, owing to the difficulty which both magnesium and sulphate ions experience in passing through membranes like the lining of the gut. But if injected hypodermically or intravenously in sufficient quantity it has a powerful action on the nervous system, causing a kind of motor paralysis and anaesthesia. This effect of magnesium—for the sulphate ion takes no part in it—has been utilized in the treatment of tetanus, in which condition magnesium salts have been injected intraspinally, with benefit in many cases in so far as the relief of symptoms is concerned. This depressant action of magnesium on the nervous system is antagonized in a dramatic way by calcium salts; an animal paralysed by magnesium being restored, in suitable cases, to a normal condition in a few seconds by intravenous injection of a soluble calcium salt.

Of the heavy metals arsenic and antimony have in recent years claimed most attention. Both arsenic and antimony have been used empirically in the treatment of syphilis for over a century but without having any great vogue. When it was discovered that organisms of the trypanosome type are the cause of syphilis and of many tropical diseases, and that arsenic is a powerful poison for such organisms, an experimental justification for the employment of this substance in the treatment of syphilis was furnished. The drawback to its use was that it is so poisonous to higher animals that it is difficult to get into the blood a concentration of arsenic sufficient to kill the parasitic organisms there present without injuring the host. It was found, however, that certain organic compounds of arsenic could be made which were very much less poisonous for mammals though their toxicity for trypanosomes was retained or enhanced. Pursuing this line of investigation of a large number of arsenical compounds Ehrlich eventually discovered and recommended, as a result of animal experiments, salvarsan as a remedy for syphilis. The value of salvarsan and of nearly related compounds in the treatment of syphilis is now common knowledge. One interesting point in regard to this is that those unicellular organisms of that type which causes syphilis readily become immune to the action of arsenic. It is therefore possible that, with the almost universal use of salvarsan nowadays, strains of syphilitic infection may be developed which are immune to arsenic; and for people infected with syphilis from these sources arsenical compounds like salvarsan would no longer have any remedial value. The risk of this unfortunate sequel is small because usually salvarsan treatment renders the patient no longer liable to infect other people and only in this way could an "arsenic-fast" infecting organism be produced, but the risk would seem to be not negligible. Fortunately no such immunity to mercury occurs.

The fact that antimony belongs to the same chemical group as arsenic suggested the possibility that it, too, might be valuable in these diseases and pharmacological investigation showed that antimony has for trypanosomes a toxicity superior even to that of arsenic. Though no organic compound of antimony has been dis-

covered comparable in advantageous properties with the salvarsan compound of arsenic, the familiar tartar emetic (potassium-tartrate of antimony) has been found, when administered intravenously, adequate for the treatment of two important diseases, Kala-Agar and Bilharzia—diseases due to organisms different from trypanosomes and for which no other effective remedy is known. These discoveries have led to a revival of the use of antimony in medicine; in the 17th and 18th centuries especially, antimony was regarded almost as a panacea, but later it lost a prestige which it is now regaining.

One of the established pharmacological actions of lead is to stimulate involuntary muscle of every kind, as exemplified in cases of industrial poisoning by the occurrence of colic caused by irregular and spasmodic contraction of the muscle of the bowel. While lead-poisoning tends to become less common, owing to trade precautions and earlier recognition of it, stress has been laid on the frequency with which lead is used, especially in industrial districts in the N. of England, to procure criminal abortion, which it tends to do—though only in poisonous quantities—by the irritant action of lead on the muscle of the uterus. For this purpose lead plaster, which is easily procurable by the laity, is frequently used by ingestion.

Of the simpler derivatives of benzol, carbolic acid itself, which was first employed by Lister as an antiseptic now over half a century ago, has gone largely out of use, especially as a surgical antiseptic, though certain closely related compounds have important antiseptic uses. Thus benzoic acid and benzoates are very widely used as antiseptics in preserved foods and are, so far as careful experiments have shown, harmless in the quantities used for this purpose. Salicylic acid has come to be a favourite antiseptic for many infective skin diseases.

The group of antipyretic derivatives of benzol continue to be widely employed not so much for reducing febrile temperatures as for their action in relieving pain, which they effect by a paralyzing action on that part of the brain which is responsible for the perception of pain. A large number of new compounds of this type have been investigated but so far only one of them threatens to usurp the supremacy of the older phenacetin and antipyrine, namely aspirin. Aspirin is a compound of salicylic acid and acetic acid. Salicylic acid and its compounds have a very important, and partly specific, effect in rheumatic fever in which they relieve the pain and reduce the temperature; but aspirin is more effective in relieving non-rheumatic pain such as headache. It is a relatively harmless drug; but occasionally alarming, if not serious, symptoms are produced by it in people specially susceptible to its action, the most frequent symptom being oedematous swelling of the face, which, however, disappears when the drug is discontinued.

Though much new work has been done on the effect of moderate doses of alcohol, little has been added which was beyond the shrewd suspicion of those who have intelligently experienced its effects throughout the ages. That it has killed more than it has cured is more than probable; that, if the imperfection of human nature persists, alcohol, if it is banished, will be replaced by something worse is not unlikely. Numerous new artificial hypnotics have been investigated, of which veronal, legitimately used, has proved safe and efficient. Unfortunately cases of veronal habit have become increasingly frequent, and deaths from overdosage, of which the lay papers have afforded numerous examples in recent years, must have served to warn the general public of its dangers.

Of the general anaesthetics ether has steadily gained in favour for routine purposes. To get rid of its irritant action on the lungs and bronchi, it has been administered in limited cases intravenously and by rectal injection, but experiments are in progress which may result in the discovery of an anaesthetic ether deprived even of the slight drawbacks which at present attach to it.

With regard to the great group of alkaloids, much light has been thrown in recent years both on their chemical constitution and their exact pharmacological actions, and no apology need be made for taking the alkaloids of opium first. These can be divided chemically into two groups, of which morphine is representative of the one and papaverine of the other. The two groups differ considerably in their actions, as might be expected. The papaverine group has a much more pronounced action than the morphine group in relieving spasmodic contraction of smooth muscle—a pharmacological explanation of the clinically observed fact that preparations of opium, which contain a mixture of the alkaloids, are better for relieving colic, for example, than pure morphine. Preparations like tincture of opium have long been used for the relief of pain by external application, in spite of the fact that pharmacological evidence was against its having any action on the sensory nerve ends, but more recent and exact research has shown that some of the alkaloids have a distinct local anaesthetic action, apart from the effect they have in relieving pain by an action on the central nervous system.

The stimulant action of caffeine on the higher functions of the brain is recognized in the world-wide practice of consuming beverages, such as tea and coffee, which owe their stimulant action to the caffeine that they contain. But caffeine also stimulates the kidneys and causes an increased flow of urine. Caffeine is chemically methyl-xanthine and two closely allied compounds, theophylline—dimethyl-xanthines—are more active while having less effect on the central nervous system, used, in preference to caffeine, where diuretic action is desired.

Cocaine is another alkaloid which was discovered as the result of the use by natives of S. America of the leaves of the coca plant as a stimulant. The active ingredient of these leaves is the alkaloid cocaine, which was found to be a powerful local anaesthetic and which rapidly displaced from use the older and less efficient remedies for the prevention of local pain. But the stimulant action of cocaine on the brain has not been overlooked by civilized races; and the habit, insidious and disastrous, of indulging in cocaine as a stimulant has become a serious problem especially in America and in France and has necessitated restrictive legislation upon the sale of the drug in most countries. This is only one of the many drugs used as a stimulant-intoxicant, others being morphine and its derivatives and the various hypnotics. When drugs having this narcotic action are taken for a very few times the person rapidly develops a craving for them. If the practice is continued, larger and larger doses have to be taken to produce the same effect, and in no long period a habit is developed, always difficult and sometimes impossible to break off.

One disadvantage of cocaine as a local anaesthetic—for example in dentistry—is that it is a very poisonous substance if absorbed into the general bloodstream in sufficient quantity and with sufficient rapidity. This danger can be prevented to a large extent, as is now the general practice, by injecting with it adrenaline which causes such a powerful contraction of the blood-vessels in the region of the injection that the cocaine is absorbed very slowly; and, as it is being excreted continuously, the risk of a dangerously high concentration occurring in the blood is minimised. Artificial compounds resembling cocaine have been manufactured which are equally good local anaesthetics but are less generally poisonous. Such local anaesthetics act by blocking the passage of impulses through the nerves, so that painful sensations can no longer pass through the affected nerve. A similar effect can be produced on the spinal cord if the anaesthetic is injected so as to come into immediate contact with it. By this method of "intra-spinal anaesthesia" the whole of the lower limbs and of the lower part of the body can be rendered insensitive to pain, because conduction of pain sensations from this region to the receiving station (the brain) is blocked at the site of injection.

The plant belladonna is said to have been so named because it was used in by-gone days by ladies fair for the sinister purpose of dilating their pupils to enhance their charms. The chief active principle of belladonna—atropine—is still in daily use for dilating the pupil, usually under more prosaic circumstances. This effect is only one example of a general action of atropine in paralysing all parasympathetic nerve terminations throughout the body. Other closely allied alkaloids found in other plants of the order *Atropaceae* have a similar action. One such alkaloid, hyoscyne, also called scopolamine, differs from atropine in its action on the central nervous system, having a depressant in place of a stimulant action, and hyoscyne is now in common use as a hypnotic for certain conditions. In combination with morphine, it is used to produce general analgesia, with temporary loss of memory, in the treatment of child-birth, for which the romantic name of "twilight sleep" has come into vogue.

Hyoscyne contains an asymmetric carbon atom and laevo-rotatory hyoscyne is much more active than the dextro-rotatory form. This difference—a superior activity of the laevo-compound—has been found also in the case of other optical isomers, e.g. of adrenaline and hyoscyamine, and seems to be very generally true.

Ipecacuanha has been used as a remedy for dysentery with varying success for nearly three centuries. It is now known for certain that it is curative only in one form of dysentery, that due to an amoeboid parasite; and also that the curative effect is due to the fact that the alkaloid emetine found in ipecacuanha is, though possibly only indirectly, a specific poison for this parasite. Emetine is now given hypodermically in amoeboid dysentery and an artificial compound of it—emetine bismuth iodide—has been found superior to it in the treatment of chronic dysentery.

Consequent upon the advances in knowledge of the physiology and pathology of the heart, the cardiac tonics of which digitalis is the chief have been investigated more fully, and a considerable part of the advantageous action of digitalis in heart disease, especially in auricular fibrillation, is found to be due to its impairing the conduction from the auricle to the ventricle.

Drugs which cause the muscle of the uterus to contract are of great value in certain cases of labour, especially for preventing uterine haemorrhage. The extract of pituitary gland, which powerfully stimulates the contractions of the uterus, has now largely replaced the preparations of ergot so long used in midwifery practice for this purpose. The active principles of ergot itself have at last been determined and two of them found to be amines—tyramine and histamine—derivatives of the aminoacids tyrosine and histidine respectively. The discovery of the wide incidence of such amines, of their physiological action and of their chemical relation to adrenaline, has formed one of the most brilliant and fruitful chapters in modern biological research and has tended to bring into closer relation and cooperation the subjects of physiology, pharmacology and pathology. (J. A. G. *)

PHILADELPHIA (see 21.367), retaining its rank as third city in the United States, had in 1920 a pop. of 1,823,779, an increase of 274,681 or 17.7% over the 1,549,098 of 1910. The pop.

of 1920 comprised whites, 1,688,313; negroes, 134,008, and Chinese, Japanese and Indians, 1,368. The increase in the white pop. since 1910 was 224,942 or 15.4%, while the corresponding increase in the negro pop. was 49,639 or 58.8%. In 1920 males were 908,067, or 49.8%, and females 915,712, or 50.2%.

Government and Finance.—The Bullitt Act, under which the city government had functioned since 1887, gave way in 1920 to the Woodward Act, which became effective with the beginning of the term of Mayor J. Hampton Moore, in Jan. 1920. The new charter differs greatly from its predecessor. Under it a dual council is succeeded by a single body composed of one member for each 20,000 assessed voters in each state senatorial district, the membership in 1920 being twenty-one. The councilmen serve for four years, and receive a salary of \$5,000. In the executive department, the department of supplies is superseded by a purchasing agent, and the department of health and public charities is separated into two with a director for each, the title "Public Charities" giving way to "Public Welfare." Further provisions enable the city to do its own street cleaning and garbage and ash removal, and place the great majority of city employees under civil service rules. By this provision not only small office-holders but the police and fire departments are removed from the possibilities of political activity.

The cost of city operations has grown steadily since 1911, when, under provisions of the state school code of May 18 1911, the Board of Education was separated from the city government. The combined cost in 1911 was \$33,846,875.91. With the school expenses eliminated the cost in 1912 of city government was \$30,213,067.44; and, barring a slight decrease in 1913, has grown steadily until it reached \$48,520,872.92 in 1919. The tax rate, with the school tax transferred to a separate item, was \$1 in 1912, \$1.25 in 1917, \$1.75 in 1918 and \$2.15 in 1920. This rate applied to real estate valued in 1919 at \$1,805,494,000. At the close of 1919, the gross funded outstanding debt of the city was \$173,473,450, of which the commissioners of the sinking fund held \$31,898,400, leaving a net funded debt outstanding of \$141,575,050.

Commerce and Industry.—As a distinctive manufacturing centre, Philadelphia shared the general depression of 1914, but advanced rapidly with the increasing European demand after the outbreak of the World War.

This is shown in the following table of the export values of the port of Philadelphia from 1910-20:—

Exports		Exports	
1910	\$65,256,949	1916	\$321,044,815
1911	70,869,648	1917	501,234,069
1912	72,769,617	1918	427,244,212
1913	72,236,967	1919	522,391,091
1914	66,256,811	1920	451,043,216
1915	132,437,556		

Importation figures also show a remarkable increase in the decade. The imports in 1910 were valued at \$89,610,401; in 1915, \$69,473,983; and in 1920, \$282,157,831. In 1910, 9,871,667 gross tons of shipping arrived and 9,771,266 tons cleared; in 1915, 9,315,157 tons arrived and 9,377,901 cleared; and in 1920, 12,246,427 tons arrived and 12,820,377 cleared. The following table of coal exportation shows the increasing value of the product as compared with tonnage shipped:—

	Coal exported in tons	Value
1910	866,148	\$2,505,745
1915	1,127,415	3,445,643
1919	1,072,773	6,434,581

This remarkable increase in the activities of the port was made possible by the completion of large parts of the 35-ft. channel from Allegheny Ave., Philadelphia, to the sea. The channel, about 800 ft. wide throughout, was 56% completed on Dec. 31 1920 (the remaining sections having a depth of 30 ft.), while a similar channel in the Schuylkill river, from Passyunk Ave. Bridge to the Delaware, was 65% completed. Both channels are national operations, authorized by Congressional action and carried on with biennial appropriations. The completion of more than half of the main channel opened the port to shipping of a heavier tonnage and the result was manifest in the increased number of lines plying from Philadelphia. In 1914 there were 27 transatlantic and 5 coastal lines; in 1918, at the close of the World War, 36 transatlantic and 4 coastal; and in April 1921, 49 transatlantic and 10 coastal lines. A survey of the Pennsylvania department of internal affairs shows that Philadelphia in 1919 had 4,454 manufacturing establishments, with 297,436 employees, and products of \$1,951,998,000. The capital invested was \$1,005,658,500. Metals and metal products were first with 946 establishments, 66,991 employees, and products of \$366,780,000. Textile factories

numbered 502, with 44,294 employees and products of \$292,107,000. The values of other products were: food and kindred lines, \$283,531,000; chemicals and allied products, \$210,240,000; clothing manufacture, \$189,629,000; paper and printing industry, \$146,510,000; leather and rubber goods, \$130,585,000; building and contracting, \$70,344,700; lumber and its remanufacture, \$41,747,700; and tobacco and its products, \$27,648,000.

History.—Municipal history in 1910-20 was marked with few items of interest outside of the political aspect and the natural effect of American participation in the World War. The late John G. Johnson, the noted corporation lawyer, who died April 14 1917, gave the city his collection of 1,300 pictures, appraised at \$4,445,802, but estimated to be worth \$7,000,000. In May 1919 the art collection of Mrs. Emily L. Harrison was left to the Pennsylvania Museum and School of Industrial Art for permanent exhibition in Memorial Hall. In Oct. of the same year, the George W. Elkins collection of paintings, containing 110 masterpieces of the Dutch, Flemish and 18th-century portrait schools, and valued at approximately \$2,500,000, was left to the city for display in the new Art Museum. In 1921 the late John Howard McFadden, a cotton broker, left to the municipality his collection of about 50 18th-century English paintings, estimated at \$2,000,000. The collection includes the famous Gainsborough, "Lady Rodney," and a number of fine portraits by Romney and Raeburn. Under the will the collection was to be housed in the projected Art Museum in Fairmount Park, provided that it was completed by 1928. In March 1921, the architects announced that it would be completed within three years.

A free library was being built in 1921, and a convention hall was planned for the Parkway, a thoroughfare from City Hall to Fairmount Park completed in 1919. Three large municipal piers were completed between 1916 and 1920 and three more were under construction. An elaborate subway and elevated transit system was being built by the city, the first line of which, to Frankford, was expected to be in operation by 1922.

War Period.—Philadelphia sent 54,127 men into the National army through the draft, and nearly equalled that figure with volunteer enlistments in the regular army, National Guard and Marine Corps. The city supplied the personnel of two full regiments of the 28th Div. and practically the full personnel of two regiments of the 79th Div., National army.

The city subscribed to the different Liberty Loans and to the Victory Loan as follows:—

Loan	Apportionment	Subscribed	Per capita Subscription
First Liberty	\$94,694,750	\$145,172,950	880
Second Liberty	139,499,950	234,901,000	130
Third Liberty	136,499,950	169,350,600	94
Fourth Liberty	259,198,000	311,306,250	172
Victory	186,209,450	208,482,200	115

(A. E. MCK.)

PHILIPPINE ISLANDS (see 21,302).—The census of 1918 gave the pop. as 10,350,640, of whom 855,368 were classed as non-Christians. The 9,495,272 Christians were in 1918: Filipinos, 9,429,857; Chinese, 45,156; Japanese, 6,684; Americans, 6,405; Spaniards, 4,015; English, 1,063; all others, 2,092. The non-Christians were subdivided into Mahomedans and pagans. In 1917 H. Otley Beyer, of the University of the Philippines, estimated the Mahomedan pop. at 315,980, while the pro-

the Romance languages differ among themselves. The English language is used currently in all parts of the islands, being spoken by more people than ever spoke Spanish. Literacy is high among the Christian population. The cultural position of the Negritos is about the same as when they were discovered by the Spanish in 1521. The so-called "wild" peoples (all pagans except for a few who have embraced Christianity) occupy about the stage of culture exhibited in the 16th century by the ancestors of the Christian Filipinos. The culture of the Christian Filipinos is distinctly occidental and is unique in the Orient.

Manila, the capital, and Baguio, the summer capital, located in the uplands, in the Mountain province, are the only two chartered cities. Manila, the metropolis, which coincides with Manila province, had in 1918 a pop. of 283,613, or 20,858 to the sq. m., and Baguio had 5,462. In the 55 provinces and sub-provinces, there were in 1918 881 municipalities, 80 municipal districts, and 15 other subdivisions. The largest municipalities in 1918 were: Cebu with 65,300 inhabitants; Albay (Luzon), with 53,105; Iloilo (Panay), with 49,808; Batangas (Luzon), with 41,182; Ormoc (Leyte), with 38,247; Laoag (Ilocos Norte), with 38,294; and Baybay (Leyte), with 36,934. The most important are Cebu and Iloilo. The most populous provinces are: Cebu, with 857,410 inhabitants; Leyte, with 597,995; Pangasinan, with 567,644; Iloilo, with 508,272; Occidental Negros, with 397,325; Samar, with 380,211; Bohol, with 359,600, and Batangas, with 340,195. The most densely populated provinces, apart from Manila, are Ilocos Sur (Luzon), with 217,410 inhabitants, or 492 to the sq. m.; Siquiljor (Oriental Negros), with 56,695, or 461 to the sq. m.; Cebu, with 450 to the sq. m.; La Unión (Luzon), with 160,575, or 459 to the sq. m.; Cavite (Luzon), with 157,347, or 339 to the sq. m.; Pampanga (Luzon), with 257,641, or 313 to the sq. m.; Pangasinan (Luzon), with 292 to the sq. m.; and Laguna (Luzon), with 195,371, or 271 to the sq. mile. The Batanes Is., a sub-province lying N. of Luzon, have the smallest pop. of any provincial division (8,214), and a density of 111 to the sq. mile. The least densely populated is the sub-province of Apayao (Mountain province, Luzon), which has 11,123 inhabitants, but only 6 to the sq. mile. The majority of the people are engaged in agricultural and allied pursuits, and among the professional classes are men of considerable attainments.

Agriculture.—Between 1913 and 1918 the cultivated area of the Philippine Islands (total area, 73,585,583 ac. or 115,026 sq. m.) rose from 5,859,877 ac. or 7.96% of the whole, to 7,294,159 ac., or 9.91% of the whole. The Filipino *hac* or peasant, naturally a good farmer, has been slow to adopt modern and more efficient methods, but through the efforts of the Bureaus of Agriculture and Education a beginning has been made in some places. In 1918 the value of the agricultural output was \$183,479,158. The nine most important crops were those of which the following table shows the area, production and value in 1910 and 1918:—

	Acreage		Production (tons)		Value	
	1918	1910	1918	1910	1918	1910
Rice	3,379,305	2,944,588	1,539,186	810,786	\$67,581,687	\$31,300,133
Abaca (manila hemp)	1,265,894	1,175,585	166,863	168,452	46,246,612	13,476,171
Coco-nuts	828,936	405,556	1,506,796,110 (number)	937,927,927 (number)	28,266,896	19,470,813
Sugar-cane	507,612	205,412	396,242	152,639	20,579,389	7,631,966
Indian corn	1,033,413	1,432,026	309,798	392,484	10,309,324	11,774,525
Tobacco	193,754	132,456	61,555	28,006	7,609,577	3,780,915
Cacao	2,820	3,151	566	74	252,335	33,406
Coffee	1,896	2,637	721	85	222,991	34,378
Maguay (aloe)	80,524	21,237	16,664	4,628	1,853,606	277,700

vincial governors of Mindanao and Sulu estimated it in 1919 at 402,799. Of the pagans, approximately 30,000 were Negritos, and most of the others belonged to Malayan stocks. Head-hunting among the pagans virtually ceased owing to vigilant Government control.

The Christians include eight races, namely, Tagalog, Sambal, Pampanga, Pangasinan, Iloko, Ibanag, Bicol, all inhabiting the island of Luzon and islands near it, and the Bisaya, inhabiting the southern islands, including part of Mindanao. Each race has a distinct language, which differs from the others as widely as

The production of rice fails to meet demand, and imports are necessary. In 1910 imports amounted to 184,620 tons, and total consumption to 712,674 tons; in 1918 imports and exports were, respectively, 159,130 tons and 47 tons; and consumption, 1,161,344 tons; in 1919 imports and exports were respectively 148,724 and 296 tons, and total consumption, 1,067,699 tons. To prevent profiteering in so vital a commodity, the Government has, in times of scarcity, purchased rice abroad, and sold it at a fair price. The cultivation of abaca has been given a new impetus by a law (No. 2380) which grades the product according to the cleaning of the fibre. Sugar is raised in almost all the islands, but chiefly in Negros, Panay and Luzon. The construction of up-to-date sugar "centrals" in many localities

PHILIPPINE ISLANDS

is redeeming Philippine sugar from the evil reputation which the "muscavado" sugar formerly bore. Corn is raised chiefly in Cebú, where the soil is especially fitted for it, and where this grain, instead of rice, is the chief crop. Tobacco is raised especially in Luzon and Cebú, the product of the Cagayan valley in Luzon being that most esteemed. Cacao comes chiefly from Mindoro I. and the Albay and Camarines in Luzon; coffee from Mindoro I. and the Mountain province (Luzon); and maguey (introduced from America) from Cebú and the province of Ilocos Sur (Luzon). An effort is being made to encourage the raising of sisal instead of maguey, the former being the better fibre. Abacá is a natural monopoly in the Philippine Islands, for it can be grown commercially nowhere else. It is grown in many of the islands, but in recent years extensive plantations have been laid out in Mindanao, where the constant moisture needed for its growth is afforded. For many years, this fibre formed one-half the exports from the islands, and is still one of the leading exports. The export of 89,438 metric tons in 1900 rose to 164,754 tons in 1910, and to 165,129 tons in 1918. Exports for 1919 fell to 131,898 tons valued at \$26,861,526, while exports for 1920 were 139,250 tons valued at \$35,862,000. The timber resources are important, virgin forests covering about 40,000 sq. miles. About 99% of all timber lands belong to the Government. Much of the timber consists of valuable hard woods. Timber land is not sold, but is developed under the licence system, small operators being granted a licence for one year, and large operators for 20 years. During 1919, 2,950 licences were issued, some of which were for gathering firewood. About 100,000,000 bd. ft. of lumber is used annually in the Philippines. Exports of lumber in 1918 were 4,178,520 bd. ft., valued at \$219,397, and in 1919, 4,503,304 bd. ft., valued at \$259,592. Modern forest products include charcoal, nipa, from which sugar and alcohol are made, various rattans and fibres, copal, tan barks, dyewoods, gutta percha and rubber, paper pulp, a soap bark, pili nuts, wax, wood-oil and medicinal plants. A school of forestry is maintained by the Government in which up-to-date, scientific lumbering instruction is given. The chief animal is the carabao or water buffalo, of which there were 1,047,164 in 1913 and 1,271,208 in 1917. Other domestic animals for these two years numbered respectively: cows, 418,114 and 603,107; horses and mules, 179,089 and 214,204. During most years of American occupation, the carabao was assailed by rinderpest, and the archipelago in 1920 was slowly recovering from its effects. The heavy mortality of carabao hampered agriculture, especially the cultivation of rice which was much retarded at times. The Government employed various methods in its efforts to eradicate the disease, including inoculation with a special serum, strict quarantine, and even the killing of whole herds.

Minerals.—Mineral products include gold, silver, iron, copper, manganese, coal, petroleum, shale, sulphur, asphalt, asbestos, clay products, lime, sand and gravel, stone, salt, and mineral waters. The total value of the mineral output in 1907 was \$117,046; in 1917, \$3,018,225; and in 1918, \$3,276,677. Between July 1 1902 and Dec. 31 1918, 10,943 mining claims were taken out, of which 6,683 were for gold, 1,893 for petroleum and 607 for copper. The gold output in 1908 was valued at \$217,250; in 1913 at \$868,362; in 1917 at \$1,408,309; in 1918 (from 24 mines) at \$1,287,985 and in 1919 at \$1,309,724. Iron-ore deposits in Surigao province, estimated to contain about 500,000,000 metric tons, with 45 to 50% iron, have been reserved for the Government. Other rich deposits are said to exist in Bukidnon province in Mindanao. The manufactured iron all came from the mines of Angac in Luzon and was chiefly used for the making of plough points. Copper is found especially in Luzon at Mancayan, where it has been mined and smelted many years by the Igorot by primitive methods. Deposits of coal are found in many localities, although much of it is lignite. Attempts have been made to develop the deposits in the eastern part of Butan I., and in 1920 the Philippine Coal Mining Co. was said to be producing about 300 tons daily. In 1919 the output was 32,892 metric tons, valued at \$411,000. Much attention has been given to the development of the coal deposits by the Government, and no little money was lost, but the industry seems at last to be on a good basis. Deposits of fair steaming coal are said to cover 58 sq. m. and to contain 61,788,000 metric tons. The National Coal Co. was organized in 1919, with Government capital, to exploit Government deposits.

Manufactures.—The Philippines have passed beyond the initial stage of manufacturing, although it is probably true that the manufacturing industries will long be limited in number. Embroideries and laces, the making of which has been fostered by the Bureau of Education as well as by some private schools, find a ready market, and during the World War when Belgium and Switzerland were unable to supply their markets, demand for the Philippine product was stimulated. The industry is still largely one of the home. Rope is made from abacá, both by the old rope-walk method and by modern machinery. Much of the abacá is stripped by machinery, although fibre cleaned carefully by hand is still the best. Saw-milling is increasing in importance, some of the mills being equipped with modern machinery. In 1910 there was only one sugar "central" in the archipelago for the production of centrifugal sugar. In 1920 there were 28, and the reputation of Philippine sugar was rising in consequence. The war gave a great stimulus to the expressing of

coco-nut oil, because of the impossibility of obtaining sufficient shipping for the export of the bulky copra. There were in 1920 more than 30 oil-mills, which produced over 100,000 tons of oil, the value of the product having increased in five years from about \$1,000,000 to about \$30,000,000 and furnishing about one-fourth of the export trade of the islands. The Philippines are the third producing coco-nut region in the world, there being over 800,000 ac. with about 68,000,000 trees, of which some 40,000,000 were bearing in 1920. The output of cigars in 1910 was 285,561,328; in 1913, 282,096,996; in 1918, 367,022,982 and in 1919, 517,343,450. The output of cigarettes for the same years was respectively 4,173,507,249; 4,384,807,247; 4,720,005,675 and 5,203,331,200. In 1918 there were 82 factories manufacturing cigars and 23 manufacturing cigarettes. In 1916 a tobacco inspection law was enacted by the Philippine Legislature providing for the improvement of the leaf and for inspection of leaf tobacco and of manufactured products, and prohibiting export to the United States unless certain fixed standards were met. In 1918 there were 10,583 factories in the archipelago, of which 1,047 were in Manila. Of the 182,117 employees, 21,828 were in Manila.

Communications.—In 1908 there were only 246 m. of first-class roads and bridges in the archipelago; in 1913, 1,303 m. of the first class; 1,264 m. of the second; and 1,937 of the third; and in 1919, 2,796; 1,235; and 1,984 m. respectively. Third-class roads are as a general rule fit only for carts and animals, and then only during the dry season. In 1919 cost of maintenance of old roads and bridges was \$1,959,780. The archipelago has two railway systems, namely the Manila Railroad Co. operating in Luzon, and the Philippine Railway Co. operating in the islands of Cebú and Panay. The first had in 1913 517 m. of tracks and in 1918 640 m. This company, under contract with the Government, partly completed a line to the summer capital, Baguio, but could not carry the project to a successful end. In Jan. 1917 the Government of the Philippine Islands purchased the company's holdings and since that period the lines have been undergoing reconstruction. The Philippine Railway Co., an American concern, had 60 m. of track in 1910 (the first year of operation), and 133 m. in 1918. Under authority of an Act of Congress, approved Feb. 6 1905, the Insular Government guarantees 4% interest for a period not to exceed 30 years on the first lien bonds issued by the Manila Railroad Co. for new construction in southern Luzon, and the same to the Philippine Railway Co. The combined issues of both companies totalled \$22,263,000. The lines in southern Luzon and those in Cebú and Panay have opened to active trade large stretches of territory and are affecting the industry of their districts. During recent years the number of motor vehicles has increased markedly, and they are now seen in almost all parts of the islands. An up-to-date electric street-railway system is operated in Manila. Post-offices increased in number from 540 in 1908 to 828 in 1918, and municipalities with free delivery service from 31 in 1908 to 462 in 1918. Telegraph offices (Government owned and operated) increased during the same period from 161 to 320. The inter-island cables are also owned and operated by the Government. Manila has an efficient telephone service.

Shipping.—Manila is the chief port, but the ports of Iloilo, Cebú, Zamboanga, and a few others share to some degree in the domestic and foreign trade. In 1911 there were 906 entries of foreign ships and 854 departures, with net tonnage of 1,849,475 and 1,787,650 respectively; and in 1918, 632 entries and 659 departures, with net tonnages of 1,412,871 and 1,544,648 respectively. The United Kingdom, which had uniformly occupied first place in the total foreign carrying trade of the islands, lost that position to Japan in 1917, but regained it in 1919, when British bottoms carried 525,000 tons. In the latter year, British and Japanese vessels carried 63% of the total foreign trade. Ships of the United States, which moved only 44,000 tons in 1916, moved 441,000 tons in 1919, while Philippine shipping engaged in foreign trade rose from 80,000 tons in 1916 to 128,000 tons in 1919. In value of cargo, British bottoms led in the import carrying trade up to and including 1917. In that year British ships carried cargoes valued at \$25,865,273; Japanese, \$18,964,331; and United States, \$9,731,816. In 1918, Japanese ships carried import cargoes valued at \$29,304,836; United States, \$28,041,294; and British, \$24,406,231. In the export trade, British bottoms also took first place up to and including 1917. In that year, British ships carried exports valued at \$28,903,609; United States, \$27,599,076; and Japanese, \$24,657,632. In 1918 U.S. vessels carried exports valued at \$53,389,398; British, \$36,093,713; and Japanese, \$24,544,204. In 1918 ships of the United States took first place in the total value of the foreign carrying trade, moving goods valued at \$81,493,692, with the United Kingdom and Japan taking second and third place respectively. In recent years new piers and warehouses have been built in Manila.

Foreign Trade.—Imports rose from \$29,186,120 in 1908 to \$149,400,000 in 1920. Exports were \$32,601,072 in 1908; \$131,100,000 in 1920. The balance of trade was in favour of the Philippines during 1914-8, and in 1920. Import trade with the United States rose from \$35,813 in 1874 to \$92,289,773 in 1920. Exports to the United States rose from \$2,657,333 in 1874 to \$105,216,263 in 1920. In 1874 the import and export trade with the United Kingdom was valued respectively at \$1,737,487 and \$3,032,950; and in 1918 at \$2,764,407 and \$19,481,698 respectively. Imports from and exports to Japan were valued respectively at \$13,104,055 and \$7,968,304;

China, \$6,576,962 and \$3,249,290; French East Indies, \$6,978,043 (mainly rice) and \$1,302,376; Hong-Kong, \$56,877 and \$5,051,664. Total trade with France was valued at \$1,785,167 in 1918; Germany, \$366,534; Spain, \$3,940,167; Australasia, \$4,431,883; British East Indies, \$3,515,885; Switzerland, \$607,870; Italy, \$189,152; Netherlands, \$45,463; Hawaii, \$479,436; Siam, \$1,219,673 and all other countries, \$1,494,421.

Government.—In 1913, upon the occasion of the appointment by the President of the United States of a new governor-general of the Philippines, majority membership on the Philippine Commission was given to the Filipinos by presidential appointment. On Aug 29 1916 the U.S. Congress passed the Jones Act. The short preamble declared that "it has always been the purpose of the people of the United States to withdraw their sovereignty over the Philippine Islands and to recognize their independence as soon as a stable form of government can be established therein." The Act created a Senate to supersede the Philippine Commission, 12 senatorial districts being established, each of which is represented by two senators elected by duly qualified voters except the 12th district (consisting of the Department of Mindanao and Sulu, the Mountain province, Baguio, and Nueva Vizcaya), whose senators are appointed by the governor-general. The Philippine Assembly was replaced by the House of Representatives, the membership of 81 of the Assembly to be increased in the new body by three representatives from the Mountain province, one from Nueva Vizcaya, and five from the Department of Mindanao and Sulu. Senators are required to be over 30 years of age, able to read and write English or Spanish, and to have been residents of the Philippines for at least two consecutive years and actual residents of the senatorial districts from which elected for at least one year immediately preceding election. Representatives must be over 25 years of age, and have the same residential qualification.

Senators are elected for six years, representatives for three. The Act extended the suffrage to males of 21 or over, to include those who under previous law were legal voters and had exercised their right; those who owned real property to the value of \$250; those who annually paid \$15 or more of the established taxes; and those who were able to read and write either Spanish, English, or a native language. Two resident commissioners with three-year terms were provided for, and paid by, the United States, to be over 30 years of age and *bona fide* electors; these commissioners to have seats in the House of Representatives at Washington, with right of debate but no vote in that body. The Legislature convenes on Oct. 16, but it may change that date within certain limits if it choose. A governor-general, vice-governor, auditor, and deputy auditor are appointed by the President of the United States, by and with the consent of the Senate. The vice-governor is in control of the Bureaus of Education and Health, but the remainder of his former bureaus and his subordinate duties were shifted to the Interior Department. Power is given to the Legislature to reorganize the other departments and bureaus of the Government. The chief justice and associate justices of the Supreme Court are appointed by the President of the United States by and with the consent of the Senate, and the judges of the courts of first instance are similarly appointed by the governor-general by and with the advice of the Senate of the Philippine Islands. The awards of the Supreme Court are reviewable by the Supreme Court of the United States.

The Government as reorganized consists of the following groups of departments, bureaus, and offices. On the governor-general depend directly the Bureau of Audits, the civil service, and all other offices and branches of the service not assigned by law to any department. On the Department of the Interior depend the Bureau of non-Christian tribes (provided for in the organic Act), the Philippine general hospital, Boards of Pharmaceutical Examiners, Medical Examiners, Dental Examiners and Dental Hygiene, Optical Examiners, examination for nurses. On the Executive Bureau depend the Philippine constabulary, and Bureau of Dependent Children. On the Department of Public Instruction depend the Bureau of Education, the Philippine Health Service, and Bureau of Quarantine Service. On the Department of Finance depend the Bureaus of Customs, Internal Revenue, Treasury and Printing, the general supervision over banks, banking transactions, coinage, currency, and (except as otherwise specially provided) over all funds the investment of which may be authorized by law. On the Department of Justice depend the Bureau of Justice, the courts of first instance

and the inferior courts, Philippine Library and Museum, Bureau of Prisons and Public Utility Commission. On the Department of Agriculture and Natural Resources depend the Bureaus of Agriculture, Forestry, Lands, Science, Weather, and matters concerning hunting, fisheries, sponges and other sea products. On the Department of Commerce and Communications depend the Bureau of Public Works, Posts, Supply, Labor, Coast and Geodetic Survey, and Commerce and Industry. The secretaries of the several departments form the Cabinet.

There are in all 46 provinces, 34 of which are regular provinces and the rest special or sub-provinces. The chief executive of a province is the provincial governor, who is elective. He together with two other members, also elective, forms the provincial board or legislative branch of the provincial Government. In the special or sub-provinces, with the exception of Mindoro, Palawan, and Batanes, the provincial governor is appointive. The chief official of a town or municipality is the municipal president. The municipal council or legislative branch of the municipal Government consists of from 8 to 18 councillors, according to the size of the municipality.

In Oct. 1918 the governor-general, by an executive order, created the Council of State as an advisory body. This body, composed of the heads of all the executive departments and the presiding officers of the two Houses of the Philippine Archipelago, has become an integral part of the governmental system and is frequently referred to in legislation. The meetings of the Council have practically superseded those of the Cabinet, and it has been entrusted by the Legislature with certain executive functions. Policies decided on in the Council meeting are assured full consideration in the Legislature. Among other things the Council prepares and submits the budget.

Education.—Special attention has been paid to public education by the Government. Each of the 49 school divisions of the archipelago follows in general provincial boundary lines, except that of Manila and four insular schools, namely Philippine normal school, Philippine school of arts and trades, Philippine nautical school, and Central Luzon agricultural school, each of which is considered a distinct division. The public-school system, which aims at the creation of a staff of English-speaking Filipino teachers, is under the director of education, with central offices in Manila. There are seven elementary grades (four primary and three intermediate) and a four-year high-school course. Much attention is paid to industrial training, and to recreational athletics. Baseball and other games have had great influence throughout the islands. Each school division is in charge of a division superintendent and each of the several districts in a division of a supervising teacher. In 1908 there were 3,932 public schools, with a total enrolment of 486,676. In 1919, 749 new primary schools and 111 new intermediate schools were opened, with an increase during one year of 104,560 pupils in the elementary grades, and a record enrolment of 776,596 pupils in all public schools. During that year, 2,963 additional elementary teachers were appointed, and 300 primary schools constructed. Tuition fees were abolished in all intermediate schools. In 1908 \$2,563,553 was spent for public education, and in 1918 \$5,365,105. The Philippine normal school, in Manila, draws its pupils from all parts of the islands. There were in 1920 50 provincial high schools, 20 provincial trade schools, 14 provincial shops, 13 large agricultural schools, 15 farm schools, and 162 settlement farm schools. The farm schools ranged in size from about 125 to 2,000 ac. and the settlement farm schools from about 40 to 125 acres. School gardens, which have become an essential part of the public educational system, number about 4,000; and home gardens, the result of this instruction, over 100,000. A standard type of school buildings has been evolved, and there were in 1920 865 satisfactory school buildings (many constructed of concrete) and 2,170 buildings of semi-permanent and permanent types. In 1910 the Government began the systematic supervision of private schools, requiring courses in English and harmonizing the work with that of the public schools. New methods, courses, and text-books have been introduced, and all private schools complying with requirements have been given the same standing as Government schools. In 1920 there were about 300 accredited private schools with a total enrolment of 38,544 and a teaching force of 1,600. Higher education is provided for by the university of the Philippines, a Government institution, and by the Dominican University of Santo Tomás. The university of the Philippines in 1920 had 31 buildings of permanent materials. The total enrolment for 1919-20 was 3,427. Its three presidents were, successively, an American, a Filipino and an American. The university of Santo Tomás, the oldest university under the flag of the United States, has departments of law, medicine, pharmacy, civil engineering, philosophy and letters, and theology. It has five buildings including a dormitory, and for the year 1919-20 had an enrolment of 701. Between the years 1914 and 1919 its graduates numbered 347. The educational programme of the islands has from the first had the hearty endorsement of the Filipino people, and Filipino legislators have at all times supported almost unanimously an movement looking toward the improvement of educational conditions. In Dec. 1918, \$15,000,000 were appropriated by the Legislature for the extension of public schools. Instruction is being extended rapidly among the non-Christian population. In addition to the education supplied in the Philippines, some 9,000 Filipinos are attending schools, colleges and universities in the United States.

some of these receive Government aid, but the majority are paying for their own instruction. The work of the Philippine library and museum is largely educational in character. This institution was first founded as the Philippine library, May 20 1909. After the passage of the Jones Bill of 1916 it was amalgamated with the Philippine archives and the museum. It has charge of all the books owned by the Insular Government. The manuscripts of the library number several millions, the books in all over a quarter of a million.

Finance.—Philippine currency in circulation on June 30 1908 amounted to 40,337,982 pesos or 4.82 per capita; on Dec. 31 1913 to 50,697,253 or 5.53 per capita; and on Dec. 31 1919 to 146,500,000, or 14.16 per capita. The Philippine peso, nominally equivalent to \$0.50 U.S., was in June 1921 quoted in New York City at \$0.46 and has even reached much lower levels; in Nov. 1921 it was quoted at \$0.4975. The total revenues and expenditures of the Insular Government for the year ending June 30 1908 were respectively, \$10,899,261 and \$11,469,785; and for 1919, \$39,843,461 and \$43,371,294. The great increases in revenues began in 1916 simultaneously with the large trade balances in favour of the Philippines. Revenues are mainly from customs collections, internal revenues and receipts from land taxes and leases. Customs collections for the year 1919 were \$7,712,653 and for 1920, \$8,878,132; and collections of internal revenues for 1919 \$26,641,373. The latter collections come mainly from the excise tax, licence, profession and occupation taxes, cedulas, franchise taxes, income tax, documentary stamp tax, and inheritance tax. The bonded indebtedness for the Insular and municipal Governments as of June 30 1919 was \$20,125,000, that for the former being \$16,000,000. Commercial bank assets rose from \$31,872,964 in 1913 to \$177,293,50 in 1919. In 1908 postal savings bank deposits were \$774,105 and withdrawals \$512,839; and in 1918 \$2,942,762 and \$2,599,775 respectively; in 1919 there were 417 postal savings banks in operation. In 1919, operations of the eight banks in Manila reached total of \$4,197,682,000. The Philippine National Bank, the sole repository of the Government, with headquarters in Manila, has branches and 41 provincial agencies in the Philippines, and branches in Shanghai and New York. Its assets on June 30 1920 amounted to \$118,749,138. More recently reverses, due, it is reported, to poor management and the business crisis, overtook the institution.

History.—W. Cameron Forbes was appointed acting governor-general in May 1909, and on Nov. 11 of the same year governor-general, succeeding James T. Smith. During his term, which expired on Oct. 6 1913, many public improvements were made, and the principle of the Filipinization of the civil service was carried out consistently, although comparatively few Filipinos were appointed to the higher offices.

The Taal volcano, which had been quiescent for a century and half, erupted on Jan. 30 1911. Some 1,300 lives were lost. The outburst was accompanied by violent earthquakes, of which 1,014 were registered in Manila in about a fortnight. Earthquakes are of frequent occurrence in all parts of the islands, but rarely of magnitude. During Governor-General Forbes's term no general appropriation measure for the expenses of Government was passed after that of 1910, because the two Houses could not agree upon the method of drawing it. In consequence, the provision of the organic Act of 1902 which provided that in the event of the failure to pass a general appropriation measure, the sum appropriated last should be considered reappropriated, was declared to be in effect, and proclamation was so made each year. The breach between the two Houses tended to widen, and much constructive legislation that would have been enacted failed of passage. Educational measures, however, were generally assured of enactment and one is continually struck by the number of measures of this kind passed by each session of the Legislature. During this period the demand for political independence by certain Filipino leaders, especially by Manuel Quezon, for part of the time lieutenant commissioner in Washington, was constant and insisted.

The Americans in the Philippines, regarded as appointees of the political party in control in the United States, were usually made to appear hostile to Filipino interests, and that impression was represented as withholding an inherent right of the Filipino people. The desire of the Filipinos for independence was and is real, and has grown with each succeeding year; the whole course of American administration has fostered this aspiration, and continually greater autonomy has been demanded, although differences of opinion have been manifested as to the safety with which this could be done.

The change of administration in Washington in 1913 was hailed with delight by the Filipinos, in the belief that it would soon lead to political independence. On Oct. 6 1913 Francis Burton Harrison, who had been appointed governor-general by President Wilson, arrived in Manila, and immediately assumed office. By presidential appointment the majority on the Philippine Commission passed to the Filipinos. Various changes were made by the new governor-general in the personnel of several of the bureaus, the chief innovation being that Filipinos were appointed to a number of the higher posts. On Jan. 1 1917 there were 31 Americans and 22 Filipinos acting as chiefs and assistant chiefs, and on July 1 1920, 20 Americans and 30 Filipinos. On the latter date there were 760 Americans and 12,047 Filipinos connected with the Government, while in 1913 there had been 2,623 of the former and 6,363 of the latter. This increased rapidly in the Filipinization of the civil service after 1913, especially of the higher offices, has been criticized on the ground of decreased efficiency, but while this was necessarily the result to a considerable extent, it was not universally so, and the policy led, as a natural corollary, to a greater official harmony than had reigned previously. In Feb. 1916 an Act of the Legislature, providing a temporary pension for employees who had been in the service of the Philippine Government for from six to ten years or longer, gave an impetus to many Americans to request retirement under the terms of that Act. While technically the provisions of the Act apply to Filipinos as well as to Americans, it has been the policy of the Government to retire eligible Filipinos only because of age or physical disability. Upon the declaration of war against Germany by the United States, many Americans resigned to enlist, and it was felt that Americans were leaving the Philippine service too rapidly, especially the teachers. A very earnest effort was made after the war to recruit American teachers.

The virtual Filipino autonomy resulting from the above-mentioned changes was increased by the enactment by Congress in Aug. 1916 of the Jones Act, by which the Philippine Commission was replaced by an elective Senate (see *Government* above). The era of good feeling, inaugurated in 1913 by the change of Government, was seen almost immediately in the passing of an appropriation measure for the general expenses of Government—the first to be enacted since 1910. Such measures have been passed annually since. One of the early Acts of the Legislature was to reduce certain salaries, especially those of the Philippine commissioners and of certain bureau chiefs; but, as in the United States, a bonus system was later adopted because of the increase in the cost of living and the governor-general recommended that salaries be increased. In 1915 the Philippine National Bank was created, taking over the former Agricultural Bank owned by the Government, which had never functioned acceptably. In the same year the Code Committee, after several years' work, finished the administrative code of the islands, which was passed by the Legislature. Among the first Acts of the all-Filipino Legislature of 1916–7 was the reorganization of the several departments of the Government, the result being that the Department of Public Instruction came to be the only one directly under an American.

The period was marked by generous appropriations for educational purposes, the most notable of these being the appropriation of \$15,352,912 for the extension of free elemental education (see *Education* above). A previous Act prohibiting the display of the Philippine flag was repealed, a measure desired most ardently by Filipinos.

Upon the declaration of war against Germany by the United States, the Filipinos offered to supply a division of troops for the U.S. army and to supply funds for the construction of a destroyer and submarine for the U.S. navy, and there was a generous subscription to the Red Cross and to Liberty bonds. A volunteer National Guard was formed, which was joined by many of the Filipino youth, this being disbanded in 1919. There were also many Filipinos who served in the army and navy of the United States. In this connexion it should be noted that Filipinos have been admitted to West Point and Annapolis. Some 22

erman ships, which had been interned in Manila harbour at the beginning of the World War, were seized after the American declaration of war, and the crews sent to an internment camp in the United States after a partly successful attempt had been made to damage the machinery and scuttle the vessels. Business during the war was brisk, notwithstanding the lack of shipping; but after the war, a depression developed from which the islands had not recovered in 1921. Governor-General Harrison resigned his post, as from March 3 1921, because of the change of administration in the United States, and Vice-Governor Yeater became acting governor-general. Shortly after assuming office, President Harding despatched Maj.-Gen. Leonard Wood and W. Cameron Forbes to the Philippines to make a complete survey and report on conditions. On Oct. 5 1921 Gen. Wood took oath of office as governor-general of the islands.

The Wood-Forbes report recommended, among other things, that the present general status of the Philippine Islands continue until the people have had time to absorb and thoroughly master the powers already in their hands," and "that under no circumstances should the American Government permit to be established in the Philippine Islands a situation which would leave the United States in a position of responsibility without authority."

PHILLIMORE, WALTER GEORGE FRANK PHILLIMORE, 1ST BARON (1845–), English judge, was born in London Nov. 1 1845, the eldest son of Sir Robert Joseph Phillimore, 1st bart., a distinguished judge and authority on ecclesiastical and international law (see 21.405). He was educated at Westminster and Christ Church, Oxford, where he had a distinguished career, obtaining first classes in classics and law, winning the Meridian scholarship and being elected to an All Souls fellowship. He was called to the bar in 1868. In 1885 he succeeded his father as 2nd bart., and in 1897 was made a judge of the Queen's Bench division, being in 1913 appointed a lord justice of appeal. He retired from the bench in 1916, and in 1918 was raised to the peerage.

As an authority on ecclesiastical law Lord Phillimore carried on the tradition of his family. He published a revised edition of J. H. Blunt's *Book of Church Law* (1872), besides a second edition of Sir Robert Phillimore's *Ecclesiastical Law* (1895), and also contributed the articles *Ecclesiastical Jurisdiction* and *Canon Law* (in part) to the *E.B.* He was from 1905 to 1908 resident of the International Law Association, and has published *Three Centuries of Treaties of Peace and their Teaching* (1917), besides issuing (1889) a third edition of vol. iv. of Sir Robert Phillimore's *International Law*. In 1918 he was appointed chairman of the naval prize tribunal. He was English representative on the commission which sat at The Hague (1920) to prepare the scheme of a permanent Court of International Justice, and was also chairman of the Foreign Office committee on the League of Nations.

PHILLIPS, STEPHEN (1868-1915), English poet (see 21.407), died at Deal Dec. 9 1915.

PHILLPOTTS, EDEN (1863–), British novelist, poet and dramatist, was born in India Nov. 4 1862, and was educated at Plymouth. He was a clerk for ten years in the Sun fire insurance office, then studied for the stage, but turned his attention to literature, producing a number of successful novels with a Devonshire setting. They include *Some Everyday Folks* (1893); *Children of the Mist* (1898); *The Human Boy* (1899); *Sons of the Morning* (1900); *My Devon Year* (1903); *The Mother* (1908); dramatized 1913; *Orphan Dinah* (1920) and a play, *St. George and the Dragons* (1919). His play, *The Secret Woman* (dramatized from his novel of that title), was refused a licence but, after a public protest by twenty-four authors, it was performed six times at matinées in 1912 under the management of Mr. Granville Barker. He also published single poems such as *The Iscariot* (1912), and two collections of poems, *Plain Song* (1917) and *As the Wind Blows* (1920).

PHILOSOPHY (see 21.440).—At the opening of the decade 1910-20, the ground covered by the philosophical sciences was so vast that any one writer could see only a small portion of it in clear perspective; and even within the partial field where he was most at home, he might well find it hard to catch the real drift of tendencies which had not fully disclosed their ultimate scope.

Among the leading philosophers of that date three distinguished representatives of already established types of thought, William James, Shadworth Hodgson and Alfred Fouillée, were shortly to pass away. In Shadworth Hodgson there passed from the scene perhaps the last survivor of the classic "British" succession of thinkers, whose characteristic method in philosophy was the direct psychological analysis of the given "moment of experience" as distinct from metaphysical or epistemological inquiry into the "transcendental" implications of Being or of Thought. His philosophy seems likely to be the last attempt to develop a system in entire independence of the influence of Kant's "Copernican revolution," unless, indeed, the recent work of Prof. S. Alexander should prove capable of development into something like a system. William James's work in general philosophy exhibits three distinct strains, none too closely connected with one another: (1) a fundamental metaphysical pluralism; (2) a radical empiricism in method; (3) the adoption in logic of a purely utilitarian theory of truth and falsehood. It was this peculiar view of truth as "that which works" or "that which produces practically useful results" which, from its apparently paradoxical character, made the principal sensation among James's contemporaries for the moment, and from which he chose the name ("pragmatism") for his type of thought; but it is open to question whether his abiding place in the history of philosophy will not depend primarily on his brilliant defence of pluralism against the singularity of philosophies of the "one substance" and "absolutist" types.

The outstanding event in 1910-2, as far as philosophy is concerned, was certainly the rapid rise of Bergson to a European reputation. *Les Données Immédiates de la Conscience* had been published as long ago as 1889, *Matière et Mémoire* in 1896, and *L'Évolution Créatrice* had reached a fourth edition in 1908, but the author's ideas can hardly be said to have attracted universal attention much before 1910. The English translations, *Time and Free Will*, *Matter and Memory* and *Creative Evolution* all belong to 1910-1. A great amount of work in various European languages appeared in exposition or criticism of Bergson's special tenets. Special reference may perhaps be made to H. W. Carr's *Henri Bergson, The Philosophy of Change* (1911), and J. McKellar Stewart's *A Critical Exposition of Bergson's Philosophy* (1912). Without attempting to pronounce on the permanent value of Bergson's ideas, it may at least be said that his works contain the most systematic and brilliant exposition of Irrationalism since Schopenhauer, and that his presentation has the advantage of exhibiting the irrationalist position unencumbered by Schopenhauer's temperamental pessimism.

Bergson's main doctrine may perhaps be briefly summarized as follows. The human intellect is itself a product of evolution, a tool fashioned by natural selection for the purpose of enabling mankind to find their way about among the inanimate bodies

which make up their physical surroundings. Hence the crowning achievement of the intellect is the creation of the science of geometry, which therefore furnishes the ideal model to which human science in general is everywhere striving to approximate. The aim of all sciences is to become exact sciences, *i.e.* sciences of number and measure. But the only magnitudes which we can measure directly are straight lines. Consequently all measurement of other magnitudes has to be effected by artifices which enable us to substitute lengths for the various "intensive" magnitudes (lapses of duration, degrees of temperature, electric charges, and the like), which meet us in the "real world" of actual life. In particular, the measurement of time only becomes possible by the artifice of representing the real duration through which we live by the image of a line on which we can measure off different lengths. This device, though indispensable to science, inevitably falsifies the facts of living experience. For it gives rise to the belief in a "Newtonian" time, which is homogeneous, like the straight line, and "flows equally," whereas the "real duration" of experience, which is the very stuff of which our inner life of feeling and conation is made, is non-homogeneous and "flows" with very varying rapidity according as we are well or ill, interested or bored, pleased or pained, and the like. From the initial substitution of the unreal "uniform" time of science for the infinitely varying "real duration," out of which the processes of life and consciousness are made, further arise all the illusions characteristic of a mechanical theory of the universe. It is our tendency to envisage time under the form of a line, which leads to the belief in permanent "substances" or things, as the bearers or supports of change, and further conducts us to the notion of a rigid determinism by producing the illusion that what happens in the various moments of time is all completely "given" at once, as all the points on a straight line are given "simultaneously." This again leads to a radically false conception of "evolution." It creates the belief that nothing radically new is ever produced in the evolutionary process; whatever emerges in the course of the process, on a determinist theory, must be already completely contained in its antecedent conditions, and adequate knowledge of those conditions must enable you to say beforehand exactly what will emerge from them. Hence for science, which to be true to its geometrical ideal must be strictly mechanical, the whole process of evolution can be nothing but the rearrangement, according to mechanical law, of selfsame and permanent units. Real life, as we know it at first hand in the act of living it, is of a wholly different kind. It is a single continuous process of becoming, in which there is no permanent substratum; it presents us at every moment with the emergence of the qualitatively new, fresh qualities, fresh adaptations to environment, which could never have been anticipated from any knowledge of what had gone before, until they had actually emerged. You cannot expect to know the direction this *élan vital*, as Bergson names the impulse which Schopenhauer had called the "will to live," will take until it has been actually taken; life is thus essentially contingent. (It follows, of course, that determinism is false as regards that special manifestation of the *élan vital* which we call will or choice. To speak of our decisions as necessitated or determined by our pasts is virtually to think of them as already made for us before we make them.) Instinctive or impulsive activity is thus but a manifestation of the forward-going *élan vital*, the tendency of the process which is life to exhibit itself in ever newer forms. Science is the inevitably unsuccessful attempt of the intellect to reconstruct the process in "geometrical" form by reversing its sense. It looks back at a process which has culminated in the appearance of something new (*e.g.* a new modification of an animal species), notes what the earlier stages of the process have been, and then assumes that it could have predicted from a knowledge of antecedent conditions the new manifestation of the *élan vital* with which it had, in fact, to be already acquainted before it could think of the antecedent events as conditions of this result. Hence, if philosophy is to understand life, its method must be the reverse of that of the scientific intellect. It must renounce the intellect and its logic, which latter is indeed merely the ab-

stract schematism of the "geometrical" procedure, and surrender itself without reserve to the intuitions and presages which attend on complete immersion in the stream of the *élan vital*.

It may perhaps be suggested that the real test of Bergson's ability to construct an irrational philosophy on this basis must be sought in the success with which it can be applied to the interpretation of the spiritual life of humanity, a task with which Bergson has not as yet fully grappled. Meanwhile, there appear to be some reasons for doubting whether the foundations of his thought are themselves securely laid. The condemnation of the intellect is based upon the assumption that because it is a "product of evolution" it can have no function but that of enabling us to find our way about among things; this is why geometry, which deals with the "surfaces of solid things," is declared to be its highest achievement, and why it is denied all value for the interpretation of life. But it might reasonably be contended that from the dawn of time men have had to occupy themselves at least as much with reaching a common understanding of one another as with learning their way about among "solid bodies," and that we should therefore expect an intellect which is a "product of evolution" to be competent to deal with life as well as with the surfaces of solid bodies. Again, it is plain that the alleged necessity for science of a spatial schematism, which inevitably misrepresents the facts of "real duration," depends entirely on the results of the one chapter (*Données Immédiates de la Conscience*, ch. 1) which expounds the author's peculiar theory of measurable magnitudes. Now this chapter bears evident marks of hasty construction. The author seems to have forgotten that even in geometry straight lines are not the only measurable magnitudes. It is indispensable that we should be able to measure angles, a consideration which of itself should have given the author pause. In fact, the whole treatment of the distinction between "extensive" and "intensive" magnitudes, upon which so much depends for Bergson's development of his theory, is, as it stands, at least perfunctory. Again, the very language employed to distinguish "real duration" from the unreal time of science, *viz.* that the portions of real duration flow with varying rapidity, seems to imply that these varying rapidities are comparable with one another, and consequently that "Newtonian" time has, after all, the significance for real life which Bergson refuses to allow.

There has been much discussion in philosophical quarters of Bergson's place in the classification of philosophers. William James, in his latest works, claimed him as a pragmatist, and it has been maintained on the continent of Europe that his doctrine is not only a form, but the one really coherent form, of pragmatism. There is, of course, a real affinity between Bergson and the pragmatists, which rests on their common distrust of the intellect. On the other hand, whereas pragmatism, at least in its inception, made it a fundamental point to insist on a pluralistic theory of the world, Bergson's doctrine of the *élan vital* is definitely singularist. Thus he touches Bradley on one side of his doctrine as closely as he touches James on the other. In fact, the complaints which pragmatists used to make a few years ago of the miraculous feats ascribed by "idealists" to the Absolute might easily be urged *totidem verbis* against the *élan vital*. According to another view, Bergson is most correctly described as a "mystic," though he can hardly be called so if the word is used with any precision. Mysticism is primarily not a peculiar way of thinking but a peculiar way of being. What the great mystics of the past have aimed at is first and foremost a transformation of human character by which it becomes responsive to stimuli from a "transcendental" world, inaccessible to ordinary perception. Since no such transcendental world is recognized in the Bergsonian scheme, it seems merely misleading to speak of his philosophy as mysticism.

A second feature of the philosophical movement in the earlier days of the decade was, in Great Britain and America, the rise of the so-called "New Realism." This also may be regarded as a conscious reaction against the idealistic doctrines of the last generation which go back for their inspiration to Fichte and Hegel, but it was a reaction which was in many ways the direct antith-

is of the movement represented by Bergson. The new realism, though it manifested itself in a great variety of forms, was in all its various guises definitely intellectualistic. This was shown by the general dissatisfaction of its representatives with the Kantian strain in the thought of their older contemporaries. What is particularly objected to, as the source of "idealistic" or "mentalistic" fallacies, is the Kantian view that both sense, in virtue of the pure forms of intuition, and thought, in virtue of its scheme of categories, are in part constitutive of the objects they apprehend. The tendency common to all the writers who may be classed together as typical of the latest forms of realism is to regard both sense and thought as simply apprehensive of data which do not depend on the perceiving mind, either for their existence or for their apprehended qualities and relations. The degree of consistency with which this doctrine is held varies with its individual representatives, but, thought out consistently, it plainly tends in the direction of ultra-intellectualism, since it leads to the view that the specific task of philosophy is simply to apprehend as completely as possible objects and relations which exist and have the characters which they are discovered by science to have quite independently of the perceiving or knowing mind. On the psychological side this tendency shows itself in its extreme form in the doctrine that known relations between objects are purely non-mental, not the "work of the mind," as T. H. Green had taught. The function of the intellect is not to create relations between its objects, but simply to discover what the relations between them are. On this point there seemed to be general agreement between such writers as Alexander, Russell, and Moore in England, Woodbridge, Fullerton, Montague and others in America, and Couturat in France. It is a natural development of the same view that the attempt should be made to deny the existence of what are commonly called "presentations," and to hold that in sense perception we have only two distinguishable factors, an extra-mental presented thing and the process of apprehending it. Presentations, *i.e.* mental "contents," which psychologists have usually regarded as immediate objects of cognition from which we may go on to infer propositions about the extra-mental things which are their exciting causes, are then dismissed as unnecessary fictions. This is the point of view adopted by Prof. Alexander, according to whom there are, strictly speaking, neither contents of cognition nor cognitive states or processes. The contents of the mind consist solely of conations of various types, and the universe is thus reduced to conative tendencies and the objects in which they terminate and find their satisfaction.

This extreme view, that presentations had no existence, was not shared by all the writers who exhibited the realistic tendency. Thus, in his *Problems of Philosophy* (1911), Mr. Bertrand Russell maintains that apart from the general predicates of things and the relations between them, which are universal and must not be said to *exist*, what we know is composed of minds, physical things and sense-data, *i.e.* what are more usually spoken of as sense-qualities: red, sweet, salt, and the like. Sense-data are neither mental (processes of consciousness) nor physical. We are acquainted directly with our own minds and also with sense-data. But we have no acquaintance either with physical things or with minds other than our own. Any knowledge we have of the minds of others or of physical things is merely knowledge by *description*, and its possibility depends on the truth that things with which we have no acquaintance can be indirectly known if it is possible to describe them in terms of sense-data with which we have acquaintance. Since Mr. Russell accepts the familiar arguments against the physical reality of sensible qualities, it follows on his theory that we have no acquaintance with physical things. I know a physical thing only by inference, as, *e.g.*, "the cause of such-and-such a definite group of sense-data." This is a description obtained by a combination of sense-data which I know at first hand by acquaintance with the universals "the" and "cause of," and with these universals I have also immediate acquaintance. My acquaintance with the meaning of "the" secures that the otherwise unknown physical thing signified by the descriptive phrase shall be strictly individual.

Thus my knowledge through sense-data of physical objects is like the knowledge I have, *e.g.* about the "magnates of the Education Department," when I know that there is such a body, and what it does, but have never met any of its members. For science, the most important point in the theory of knowledge is that we can be directly acquainted with relations and universals, though these entities do not properly exist: Immediate knowledge of this kind is what we mean by a *priori* knowledge, *i.e.* knowledge which does not involve awareness of any proposition about what actually exists. As the principles of inference are among the relations with which we have acquaintance *a priori*, we are able to have a derivative *a priori* knowledge of all truths which are deduced by correct inference from *a priori* principles with which we are directly acquainted. This covers the whole domain of the sciences of logic and pure mathematics, as, contrary to the Kantian opinion, all pure mathematics can be shown to consist of propositions deduced logically from premises which involve only logical concepts and relations with which we are directly acquainted. It is added that we must also include under *a priori* knowledge our direct acquaintance with the relative intrinsic worth of various goods. This is why there can be a science of ethics. The chief special work of the particular type of realism represented by Mr. Russell and his associates was done, in close connection with the earlier work of mathematicians like Peano and Frege, in the field of mathematical logic, with a view to the exhibition of pure mathematics as a vast body of deductions from the principles of the logic of relations, first treated with due elaboration in the third volume of E. Schröder's *Algebra der Logik* (1895), and applied with particular thoroughness to arithmetic in Frege's *Grundgesetze der Arithmetik* (1893-1903). The *magnum opus* of Messrs. Whitehead and Russell, *Principia Mathematica*, represents the fullest development of logic as a calculus of relations. The most brilliant account of the principles and methods of the mathematical logicians is, perhaps, that of Couturat (*Principes des Mathématiques*, 1905).

Russell and also G. E. Moore made some application of their doctrine to ethics (see G. E. Moore, *Principia Ethica*, 1903; *Ethics*, 1912; and Russell, *Philosophical Essays*, 1910), but without any very satisfactory results. From their point of view the principal business of ethics is to discover true propositions about the relative intrinsic worth of different "goods." As both writers assume that there are a plurality of such propositions, and that each of them is known *a priori* independently of the others, the impression they leave upon a reader not previously committed to their theory is that they have really no better standard for determining the worth of various goods than their own personal preferences. It is characteristic of both writers that they assume without serious inquiry that conduct can only be good in a derivative sense as leading to the production of some good other than itself. Hence, though both reject the older forms of utilitarianism as ascribing a fictitious worth to pleasure, their own doctrine is itself utilitarian in its general character. Beyond discovering true propositions concerning the relative worth of goods, ethics seeks to furnish rules of right conduct, *i.e.* conduct which produces good results, but these rules are always of the most rough-and-ready sort and constantly require modification to suit special cases. Hence the ground is left open in practice for an enormous development of reflective casuistry. Messrs. Moore and Russell have furnished us with some acute observations on the relative goodness of various objects, but because of their refusal to look at human life as a whole they cannot be said to have advanced the study of ethics as an interpretation of life. In their ethical writings, slender as they are in bulk, one cannot see the wood for the trees; they are too much occupied with the search for true propositions about "goods" to develop a satisfactory theory of "the good."

Besides the irrationalism of Bergson and the atomistic intellectualism of the new realists, one may mention as characteristic of the years preceding the World War a third tendency, which held in some respects a middle place between the former two. This was the revival of philosophical Theism, in connection with which important work was done, especially by Prof. James

Ward, Dr. Rashdall and Prof. Bernardino Varisco. Ward and Varisco agree in refusing to accept the unfavourable verdict of pragmatism and Bergson on the worth of the intellect in philosophy, and are so far pronounced rationalists as to require of any philosophical theory of the world that it should be able to justify itself before the bar of reason; neither is, however, an "intellectualist," since neither ascribes to cognition a primacy in importance for the philosophical interpretation of the world over feeling and conation; and both admit, like Kant, our right to believe what we cannot demonstrate, provided that such belief, if accepted, would form the natural completion of the conceptions to which strictly logical analysis of the contents of science points. Both hold in common with Bergson and the pragmatists the reality of contingency and the production of the genuinely "new," but both deny that there is anything irrational or repugnant to the intellect in these conceptions. Ward's views find their development in his *Realms of Ends* (1911), Varisco's in *I Massimi Problemi* (1910) and *Conosci te stesso* (1912). Both thinkers show very markedly the influence of Lotze, whose final results in the main agree with theirs; Ward is, on the whole, Kantian, Varisco Leibnizian in manner.

Ward's starting point is afforded by the contrast between the unity which thought demands of its world and the apparent plurality which meets us in the world of sense perception. The problem which philosophy has to solve is, according to him, on what lines the world of experience can be thought of as one without our ceasing to recognize that it is also truly many. The history of the post-Kantian "idealist" schools has demonstrated that the problem is insoluble if we attack it from the side of the "one." Since the world of perception is not primarily given to us as one but as many, we have to start from its given multiplicity and work toward such a final conception of its unity of plan as our data will permit. Ward thus begins by a tentative inquiry how far the metaphysical assumptions of pluralism will allow us to recognize the experience-world as exhibiting unity. This leads him, *inter alia*, to a brilliant criticism of the concepts of mechanism and "evolution" as they figure in singularist philosophies. The result of the criticism is much that of Bergson's critique of the "geometrical" bias ascribed by him to the intellect. A mechanistic monism must reduce "evolution" to a process by which things unfold what has all along been in them in an "incapsulated" form; but the process known to genuine science by the unhappy name of evolution is really more properly "epigenesis," the growth of the qualitatively new, and therefore unpredictable, out of the old. Starting with an original pure pluralism which resolves the course of things into interactions between agents, each of whom is independent of any other, we can see that a pluralistic universe would develop a tendency to unity in the very process by which its members establish a *modus vivendi* among themselves, but it is uncertain whether such a tendency would give us the amount of unity we presuppose in the real world when we assume the validity for it of general laws, and it certainly does not warrant our ascribing to it such a unity as would justify the belief that the universe is such as to permit the realization of our moral and spiritual ideals. If, however, the pluralist should modify his hypothesis by regarding one member of his universe as a God from whom the rest derive their real but dependent existence, we could find in the existence of such a God good ground for faith in the persistence of spiritual life after bodily death, and the final victory of good over evil; the alleged difficulties of Theism, in particular the alleged impossibility of reconciling the goodness of God with the presence of evil in His world, have no conclusive force. Thus we are free, as Kant held, to exercise a reasonable faith in God and in immortality; and such a faith, while meeting the demands of morality and religion, involves no breach with the intellect, as it amounts only to a further step along the road which the pluralist is forced to tread in accounting for the presence of even so much unity of plan as he has to admit in the visible world.

Varisco reaches a very similar position as the result of a polemic against the empiricist metaphysic of the ordinary Comtist. He begins with an analysis of the actual moment of sense per-

ception. The objects apprehended in such perception stand at once in two sets of relations. On the one hand, they are connected in various ways with one another, and as so connected they form a system which lies open to the perception not only of the special "I" who speak of apprehending them, but to the perception of innumerable other beings, each of whom can equally say "I apprehend" them. Considered from this point of view the system of sense-data and their interconnections may be said to form the common perceived world of mankind at large. But also a given sense-datum which I apprehend is, at the moment of its apprehension, present along with experiences (feelings, conations) which are intimate and private to me and directly accessible to no other being which calls itself "I." In this sense the perceived objects may be said to be *my* objects. Thus there is a sense in which the whole world of fact to which the individual has to adjust himself in action is inseparably bound up with the individual's inner life. Varisco develops this idea in a way which may remind us strongly of T. H. Green, but is at least equally reminiscent of Leibniz, the one great philosopher whom Green persistently misunderstood. It is fatal to the empiricist theories which regard the "external world" as simply given in sensation that the world reveals itself to science as a complicated network of relations between terms, and neither the universals which pervade it nor some at least of the terms they connect are sense-data. The universals are apprehended by thought, and the self to which they are known, the only thing which we apprehend directly as it is, is also no sense-datum. It is our immediate non-sensuous apprehension of the self which owns its "states" that supplies us with our standard of real Being. Hence Varisco is led to postulate as indispensable factors in the scheme of the universe not only the sense-data and the system of relations between them, but the plurality of persons whose sense-data they are and whose thought apprehends their complicated relations. From these considerations follows the reality of freedom and contingency. For each individual has its unique qualitative character, by which it is distinguished from every other, and the course of phenomenal events thus depends on two factors, the unique characters of individuals and the universal relations between them, and the former factor is obviously incalculable with certainty just because it is what is not common to two or more individuals. Hence the actual course of things is only partly calculable, and this admission of contingency, or spontaneity in the individual, involves no breach with the principle that it is for philosophy to satisfy our intellectual demands. We may call the element of spontaneity a logical (since logic is concerned solely with the universal laws of interconnection and interaction), but not irrational.

At this point arises the supreme issue for a philosophical interpretation of the universe, an issue which is one of value or worth. The question is whether we regard the principle of organization in the universe as immanent, and manifesting itself in an endless succession of individuals which are all transitory; or whether we are to think of it as itself a transcendent individual, and of the finite individuals in which it exhibits itself as permanent factors in the universe. In the former case, the values of the individuals will be all relative, and there will be no meaning in attaching value or purpose to the world-order itself, as it is only the individual which properly has either; in the second case, there will be a meaning in regarding the values we ascribe to human personalities as absolute, and we shall be able to ascribe value and purpose to the universe as a whole, no less than to its various members. Varisco's view is that philosophy as such cannot decide this issue between an impersonal immanent principle of order and "the traditional Christian conception of God." Our decision will turn upon the intensity of our faith in the correspondence between the order of facts and our spiritual ideals. His own preference is for the Christian solution, as an expression of personal faith.

In the sphere of ethics, the attention of modern philosophers of all schools has seemed to be more concentrated on the inquiry into the presuppositions and methods of science than on the interpretation of our inner life. "*Erkenntnistheorie*" is more

in the fashion than "discourses on conduct." This is, as has always been the case, specially true of the work of the Neo-Kantians. Special notice is perhaps due to the important volume, *Substanzbegriff und Funktionsbegriff* (1910), by the distinguished Neo-Kantian writer, E. Cassirer, which is specially valuable for its insight into the real character of the universals, or laws, of exact physical science, and for its criticism of the work done on the philosophy of mathematics by distinguished "new realists." In the sphere of "philosophy of religion" one may perhaps give special commendation to Evelyn Underhill's brilliant attempt to make a thorough study of the meaning and worth of the mystic "way of life" (*Mysticism*, 1910), as well as to the important and elaborate restatement of the principles of "idealism," with special application to the problems of religion, by Prof. B. Bosanquet in his *Principles of Individuality and Value* (the Gifford Lectures at Edinburgh for 1911) and its sequel, *The Value and Destiny of the Individual* (Gifford Lectures, 1912).

It was not much easier in 1921 than it might have been in 1910 to detect a single main stream of tendency in latter-day philosophical thinking. Perhaps, however, it may be said that some of the issues were slowly clarifying. Except possibly in Italy, where the Hegelian influence was marked in the work of Croce and Gentile, "absolute idealism" of the Hegelian type seemed to be losing ground. The veterans of the movement continued to produce impressive work. (It may be sufficient to mention, in addition to B. Bosanquet's two volumes, F. H. Bradley's *Essay on Truth and Reality*, 1914, and J. M. E. McTaggart's *The Nature of Existence*, vol. i., 1921.) But, at least outside Italy, the school no longer seemed to attract recruits among younger men. "Pragmatism" (or "Humanism") seemed also, since the death of William James, to have taken its place definitely as a movement which had "done its do," and Bergson to be on the way to that canonization as a "classic" which means, among other things, that the canonized is felt to belong to the past rather than to the present. Nor had the philosophy of pure mathematics produced any work of absolutely first-rate importance since the third volume of the monumental *Principia Mathematica* of Whitehead and Russell. In 1920-1 the remarkable developments given to the doctrine of "Relativity" in physics by Einstein and others seemed to have caused a displacement of the centre of gravity of "epistemological" discussion. For some time to come the most topically interesting problem for the "epistemologist" and the metaphysician was likely to be the evaluation of the new physical ideas from the standpoint of general philosophy, and perhaps the most significant fact in quite recent philosophical literature in the English language was the impression which had been produced by Whitehead's two remarkable volumes, *Principles of Natural Knowledge* (1919) and *The Concept of Nature* (1920). The future would show whether these works might not give rise to a new and brilliant *Naturphilosophie* with marked affinities to Plato in the *Timaeus* and to Berkeley. For the present, physics seemed likely to occupy the same sort of central position in philosophical speculation which mathematics had held since 1900.

As far as could be discerned in 1921, the main directions in contemporary philosophy seemed to be three.

(1) Theism of a strongly ethical kind with a metaphysical basis of "monadism" or "personal idealism" and definitely hostile to that depreciation of human individuality which was common among the religiously minded idealists of the latter part of the nineteenth century. The theists of this type commonly call themselves "idealists" and hold fast to the conception of a real unity of the world of persons in a supramundane God, whom the world would not refuse to speak of as "personal," though some of them would hesitate to call him a "person." Striking examples of valuable works from this standpoint are James Ward's *Psychological Principles* (1918—the most philosophical treatment of psychology so far produced in Great Britain or perhaps in Europe); W. R. Sorley, *Moral Values and the Idea of God* (1918); A. S. Pringle-Pattison, *The Idea of God* (1917); C. C. J. Webb, *God and Personality* (1918); *Divine Personality and Human Life* (1920).

(2) "Neutral Monism" in its various forms, all agreeing in the attempt to deny that disparateness of mind and matter upon which Descartes taught modern philosophy at its very inception to insist, and the desire, speaking generally, to reduce the importance of mind, "consciousness," "the subject" in the scheme of things, to a minimum. This tendency has, perhaps, been most marked in the United States of America, where it has given rise to a whole school of young metaphysicians calling themselves "New Realists" (in contradistinction from the older realists of the Aristotelian tradition) and has been carried into psychology, with some exaggeration of its distinctive point of view, by the so-called "Behaviourists."

In Great Britain the same tendency has been shown in the later work of B. A. W. Russell, but its most striking product was perhaps S. Alexander's *Space, Time and Deity* (1920), where the principles of "New Realism" are combined with the speculations of Minkowski, Einstein and others on "Relativity" in an attempt to take stock of the universe and its contents. As the result is to represent these contents as an hierarchical order in which mind, however low its real rank, at least holds the highest rank with which we are acquainted, it is perhaps not unfair to say that, in Mr. Alexander's construction, relativity is at any rate "relatively" more prominent than "new realism." There is a certain community of temper between the work of the "New Realists" and one or two important works on special topics which do not commit themselves unreservedly to any metaphysical standpoint, though they may fairly be said at least to be not "idealistic," such as C. D. Broad's *Perception, Physics and Reality* (1914) and J. Laird's *Problems of the Self* (1917). J. Laird's later work, *A Study in Realism* (1920), is much more decidedly in line with the "new realism," though (as might be expected from an author whose earlier book was chiefly notable for the vigour with which it defended the position that the self, while unquestionably real, is neither the body nor any part of it) free from the tendency of many "new realists" to depreciate the importance of mind in the scheme of things.

It was as yet too early in 1921 to feel sure what the value of this revival of "realism" was. As against the older tendency to regard Nature as very largely the creation of the human mind and, in fact, something of an "illusion" which happens unaccountably to be shared by every one, it may fairly be said to be largely justified, and it seems also likely to prove a serviceable ally to the moralist who believes in "objective" obligation against the perennial endeavour of the mere anthropologist to confound moral distinctions with capricious "personal" likings and dislikes. It is a strong point of the doctrine that it refuses to regard the universals of science and ethics as "figments" (like the older sensationalism), or (like Kantianism) as "creations of the mind." They are genuinely there "in the facts," and have to be accepted no less than the deliverances of sense as "part of the facts." In so far as the "realistic" tendency seems likely to deliver us in natural philosophy from the belief in a "material substrate" and the rejection of the wealth of "sensible qualities" to the realm of illusion, and in ethics from the theory that moral values are purely "subjective," it promises to do admirable work for the clarification of thought. But it may be suspected that some of the protagonists of the movement are too much in a hurry to philosophize with due discrimination. The "neutral monism" to which they seem to tend in metaphysics is no new thing, and one may doubt whether it really deserves to survive its drastic criticism by J. Ward at the end of the last century (*Naturalism and Agnosticism*, 1899). It seems probable that some of the dialectical victories of the "realist" are easily won by substituting the alleged dualism of matter and mind for the very different duality of knower and known. To deny that the universe consists of two classes of substances, radically distinct and disparate in all their properties, is one thing; to maintain, as some, if not all, "new realists" do, that minds might disappear from the universe and yet leave it with all its colours, tones, odours, perhaps with all its "values," unaffected is quite another. Reference to the "subject" of knowledge may be irrelevant to the discussion of particular problems in nature precisely because

the "subject" is equally relevant to the whole of Nature. To the present writer, at least, it seems that none of the "realists" of the moment has so clear an insight into the real significance of the "subject" and the real character of "Nature" as was shown long ago by John Grote in his remarkable, but unfortunately not very readable, work *Exploratio Philosophica*.

(3) The third tendency which calls for note is what one may call "Spiritualist Pluralism." According to this view the universe consists in the end of a vast plurality of minds, but there is no one central and supreme mind controlling its destiny. Anti-materialism and atheism are thus conjoined. The view itself is, indeed, not a new one. It has been long upheld, as an interpretation of Hegelianism, by J. M. E. McTaggart, and is, of course, not so very different from the "theism" of those "personal idealists" who make a point of objecting to the traditional doctrine of the Divine Omnipotence. But the pluralistic universe of spirits, as conceived by these thinkers, is, of course, an orderly one. The believers in a "finite God" have always stipulated that the limits of their Deity's knowledge or power shall be so widely drawn as to leave Him in a position to act as an overruling Providence to the rest of us. McTaggart's scheme does not include a God at all, but, for reasons which he has, perhaps, not made fully apparent, he is persuaded that it is in the nature of spirits to fall into line with one another and even to advance inevitably by a natural law to complete fruition of perfection and happiness. His world, to use an illustration of his own, is like the senior common room of a college without a master. (Have we here a last vestige of the old, comfortable Godwinian dogma of the "perfectibility of human nature"? There is a distinct flavour of the 18th-century optimism, against which *Candide* was a protest, about this metaphysic. The times of violence, it is taken for granted, lie behind us in the dim past; "culture" and "enlightenment" are a sufficient guarantee against their return, exactly as was thought by those representatives of the French *noblesse* who came up to Paris for the meeting of the States-General in 1789.) Naturally enough, the events of the recent years of world-wide war (1914-8), which made even the most optimistic feel how very insecure the foundations of our "moral civilization" are, were not favourable to spiritualistic pluralism of this easy-going and cheerful kind. Aerial bombardments and poison gases brought it home to all of us that the world is as "dangerous" as Nietzsche could have wished it to be. But an anarchic version of spiritualistic pluralism was enunciated with great vigour at the end of the war by the brilliant Italian philosopher, A. Aliotta, who had formerly professed a theistic "personal idealism," in his small but striking manifesto *La guerra eterna ed il dramma dell'esistenza*. According to Aliotta, what the "real world" of spirits resembles is not a college in the long vacation but one of the fronts of the recent war. Spirits are ingenerable and indestructible, and their life is an unending warfare for incompatible ideals. The issue of the conflict is unknown and unknowable, and, indeed, it is just the fact that it is unknowable which makes the fight worth while. It seems even to be held that good would not really be good unless there was some one to hate and resist it. *Arma amens cupio nec sat rationis in armis*. Aliotta, in his later phase, rejects Theism with disdain. His reasons appear to be primarily ethical. If there is a "God above," it is argued, we know already that the issue of the secular warfare of good with evil is decided. Good is going to win and we know it; the battle is thus as good as over already, and there is no more heroism in playing a man's part in the world than there is in charging an unloaded battery on a day of field manoeuvres. Aliotta's zeal and energy have created, apparently, a whole band of enthusiasts for a pluralism of this kind among the younger Italian philosophers. The weak points in the intellectual construction are, however, obvious. The alleged ethical objections to Theism only hold good on the assumption that Divine Providence is absolutely incompatible with human freedom, and no serious attempt is made to justify this assumption that Theism means hyper-Calvinism. That in a theistic universe good will be triumphant "in God's good time" may be certain, but it does

not follow that it will triumph without our efforts or that it does not depend largely on us when that "good time" shall be. Again, it must not be forgotten that the Theist does not commonly profess to be able to demonstrate his creed with mathematical certainty. He lives by faith and hope and usually professes to *prove* no more than that the scheme of things leaves him room to hope. It is probably impossible to reason an intellectually alert but morally frivolous man into belief in God. Still more unreasonable does it seem to hold, as Aliotta and his followers sometimes appear to hold, that the very meaning of "good" is "something which one has to fight for." If this were so, evil would clearly become very good if it were so generally hated by most men that its partisans were compelled to fight very hard on its behalf. It must always be more than a meaningless form of words to ask the question: "Is what you propose to fight about worth fighting for?" To put it differently, the proposition "that for which I am fighting is good" is always a synthetic proposition in Kant's sense of that phrase.

The years from 1918 to 1921, at all events in Great Britain, seem to have been rather barren in works of practical philosophy of outstanding importance. There were, of course, many reasons for this: the disturbance, by the war, of the ordinary avocations of the class by whom such works are chiefly produced, the rise in the cost of living which lowered the demand for books, and above all the great increase in the cost of paper and labour. Mention should, however, be made of one admirable work, L. T. Hobhouse's, *The Metaphysical Theory of the State* (1918). Hobhouse's work is a hostile criticism of the Hegelian tendency to deify the State as a sort of "super-person," which he takes as exemplified by B. Bosanquet's *Philosophical Theory of the State*, and a reassertion of the traditional "liberal" conception of the State as a system of machinery for the promotion of the welfare of individuals. The criticism of the Hegelian adoption of Rousseau's conception of the "general will" is severe but illuminating. It may be that Hegelianism tends to make men conservatives (though our own Hegelians have as often been socialists), and that Hobhouse's personal political inclinations at times run away with him. He seems so convinced of the antecedent probability that any governmental enactment will be a bad one as almost to hold that any "rebel" (a Marat or an Hébert?) may be presumed to be in the right until it is proved that he is in the wrong. But in view of the dangerous tendency of present society to "look to Government" for everything, and of the serious moral abuses to which the metaphor of the "personality" of the State may lead when it is taken to be more than a metaphor, the book must be regarded as a singularly timely contribution to philosophical politics.

In pure logic perhaps the most important English publication of very recent years has been the issue in 1921 of the first volume of W. E. Johnston's long-expected *Logic*. Mention should also be made of B. Bosanquet's *Implication and Linear Inference*, a welcome appendix to the more voluminous logical work of the veteran philosopher which throws a good deal of fresh light on his fundamental position.

The years of war and uneasy reconstruction have not been barren of useful work in the history of philosophy. In N. Kemp Smith's *Commentary to Kant's Critique of Pure Reason* (1918), we have at last in English an adequate historical and exegetical companion to the most famous of all German works on metaphysics and the theory of knowledge which will be indispensable to all serious students and may take rank with anything which the Germans themselves have done for their illustrious philosopher. If Smith's work is not quite on the gigantic scale of Vaihinger's great German commentary, it has the advantage of covering the whole of the *Critique*, whereas Vaihinger breaks off at the end of the *Transcendental Aesthetic*. In all other respects the British commentator may fairly sustain comparison with his Continental predecessor. Another very welcome contribution to the history of modern thought is J. Gibson's *Locke's Theory of Knowledge* (1917), which should do a great deal towards making the real greatness of Locke as a rationalist philosopher clear to his countrymen and dispelling the strange conception of him as

a sensationalistic empiricist made current among us in the 'seventies of the last century by T. H. Green's *Introduction* to the Green and Grose edition of Hume. It were much to be wished that some competent scholar would do for Hume, a philosopher who has been no less strangely misunderstood, what Gibson has done for Locke. We still need to have it established by a really historical study of the *Treatise* and the dialogues on *Natural Religion* that Hume was neither an empiricist, as Green would make him, nor a positivist, as Huxley represents, but precisely what he calls himself, an "academic or sceptical" philosopher, and that the true measure of his intellectual greatness can only be taken when this simple fact is kept steadily in mind. A gap is also filled in our philosophical literature by the appearance of W. R. Sorley's *History of English Philosophy* (1920), which begins with Alcuin of York and carries the story down to the end of the 19th century. The veteran J. T. Merz completed his masterly *History of European Thought*, a work to which it would be hard to find a parallel in its scope and the accuracy of knowledge in many fields which it displays, by the issue of the fourth volume in 1914. He has since given us an interesting addendum, containing an outline of his own philosophical interpretation of experience in *A Fragment on the Human Mind* (1919), where it is interesting to see how profoundly a thinker at home in all the developments of French and German thought has been influenced by our own Berkeley and Hume. The *Fragment* is one of many signs that there is possibly a great future before a really critical Neo-Berkeleyanism. Berkeley received scant justice at the hands of the Anglo-Hegelian "Idealists" of the late 19th century, who seem to have been under the impression that his best-known doctrine was meant as a kind of "subjectivism." The 20th century seems likely, by laying stress on the very real element of "naïf realism" in his work, to arrive at a more intelligent and more generous estimate of its permanent value. We should not omit to chronicle the real service done to philosophical literature by the Open Court Publishing Company in the reissue (1916) of the epoch-making work of Boole on the *Laws of Thought*, the original edition of which had become very scarce. It is a great misfortune, owing presumably to the deaths of Dr. Paul Carus and Mr. P. E. B. Jourdain, that the complete republication of the logical writings of G. Boole and his great contemporary Augustus De Morgan has not been proceeded with. A reprint of De Morgan's *Formal Logic*, his contributions to the logic of relatives, and *Trigonometry and Double Algebra*, if of no other of his works, is badly needed by the student of the history of modern exact logic.

It is gratifying to note that the study of the great Greek founders of science and philosophy is still zealously prosecuted in Great Britain and in other countries, notably in Italy, which has been remarkably fertile in recent years in all departments of philosophical literature. It may be recorded that all through the war the issue of the great Oxford translation of Aristotle provided for by the will of Jowett slowly proceeded, the last part issued up to the middle of 1921 being the revision of Jowett's own version of the *Politics* by W. D. Ross. The Aristotelian student may be excused if he feels a little impatient at the continued non-appearance of just those Aristotelian works which are at once the most interesting and the least adequately represented in English, the *Organon*, *Physics*, *De Caelo*, *De Generatione* and *Meteorologica*. But for these logical and cosmological writings the English Aristotle was in 1921 well-nigh complete. Another most valuable work which progressed steadily after 1914, and in 1921 needed only one more volume to be completed, is the handsome edition of Kant's works with that indispensable *subsidiūm*, a full collection of variant readings edited by the eminent scholar, E. Cassirer. If, in binding and quality of paper, the later volumes inevitably fall off to some extent from the high standard of the earlier, this edition is in all other respects what an edition of a great classic ought to be. It was at last possible to read Kant with pleasure to the eye and with full certainty whether what one had before one was what Kant himself actually allowed to be printed or a (good or bad) conjecture of some modern Kant-scholar. We have too long acquiesced, and that not only in

philosophical works, in a standard of textual accuracy where modern writers are concerned which would be rightly deemed barbarous in editions of the Greek and Latin classics. It is to be hoped that this bad practice will not be tolerated much longer by self-respecting scholars.

The changes in the third edition (1921) of J. Burnet's *Early Greek Philosophy*, the most critical and careful study of the beginnings of Greek science, are an interesting indication of the advance our knowledge of classical antiquity had made since 1908. No contemporary work on the primary Greek philosophers is of quite such first-rate importance as L. Robin's important *La Théorie Platonicienne* of 1908, the one modern work which systematically and in detail begins the investigation of Plato's philosophy with the proper initial question, what Plato was understood to mean by men like Xenocrates and Aristotle, who heard his doctrines from his own lips. J. Burnet's *Greek Philosophy, Thales to Plato* (1914) proceeds on similar lines, but the writer is limited by the facts that Plato is only one part of his subject and that he has perforce to give most of his space to the exposition of the dialogues. His actual interpretation of Plato was deferred to his second volume, not yet published in 1921. But Robin had issued a brief but important appendix to his main work, *Études sur la signification et la place de la Physique dans la Philosophie de Platon* (1919). Mention should also be made of the admirable Platonic studies of Adolfo Levi, *Sulle interpretazioni immanentistiche della filosofia di Platone* and *Il Concetto del Tempo nella filosofia di Platone* (1920). These are contributions of first-rate importance to the recovery of the genuine tradition of the first generations of the Platonic Academy. It ought to be clear that it is on the recovery of this tradition, for which there is ample available evidence, that our hopes of definitely ascertaining the real meaning of the first and greatest of all philosophical writers must depend.

The Neo-Thomist movement in the Catholic universities of the Continent still continued, in 1921, to flourish vigorously and to show its vitality in the general excellence of the work in such journals as the Italian *Rivista di Filosofia Neo-Scolastica* and the *Revue Neo-Scholastique de Philosophie* issued by the philosophical faculty of the university of Louvain. Among the actual books produced quite recently by the movement, mention may be made of the brief but highly condensed and valuable study of St. Thomas's thought in its entirety, *Le Thomisme*, by E. Gilson of the university of Strassburg. The English reader will get an admirable introduction to a great philosophy too little known among us by combining the study of this general introduction to Thomism with that of the very sympathetic exposition of Thomist natural theology by P. H. Wicksteed, *The Reactions between Dogma and Philosophy Illustrated from the Works of St. Thomas* (1920). The appearance of works like this last leads one to hope that it might soon be impossible for the average historian of philosophy among us to write as though nothing of any significance had been thought or said in philosophy between Plotinus (or even Aristotle) and Descartes. Two other recent contributions to the study of ancient and mediaeval thought may be mentioned. G. M. Stratton's *Greek Physiological Psychology* (1917) is a painstaking and laudable attempt to edit the important fragment of *Theophrastus de Sensu* with a translation and full explanatory commentary. In *Opera hactenus inedita Rogeri Bacon fasc. V.* (1920), A. G. Steele happily resumed the task, interrupted by the war since 1913, of providing a complete edition of Roger Bacon's writings.

In U. von Wilamowitz-Moellendorf's two large volumes entitled *Platon* (vol. i., 1917; vol. ii., 1919), the veteran German professor makes some interesting and valuable suggestions, but he is debarred from acting as a competent interpreter of Plato partly by complete lack of training in philosophical thought, partly by a habit of treating ingenious guesses of his own about the motives of a classical writer and the circumstances in which his various works were composed as certainties, partly by a curious want of finish in verbal Greek scholarship which makes his long series of conjectural emendations, in spite of a few felicities, into a systematic depravation of the Platonic text.

During the decade, many of the familiar figures of the philosophical world were removed by death. This was only to be expected in the case of octogenarians like Wundt and Windelband and J. F. Brentano, still more in that of a nonagenarian like the Italian positivist, R. Ardigò (1828-1920). In Great Britain there were few losses among the elder philosophers since the death of the nonagenarian, A. Campbell Fraser. Of the elderly, but not old, the United States lost their leading philosopher, Josiah Royce; France, Gaston Milhaud and Émile Boutroux (1845-1921); and Austria, Alexis Meinong. Still more regrettable was the death of men who were still young or in their intellectual prime, as Louis Couturat in France and Oswald Külpe in Germany.

(A. E. T.)

PHYSIOLOGY (see 21.554).—Since 1910 increased attention has been paid, in physiological research, to phenomena common to living beings in general, and recent investigation has added considerably to our knowledge and corrected earlier theories.

As distinguished from *Morphology*, the science of the form and structure of living organisms, *Physiology* may be said to be concerned with their activities, chemical and physical. But there can be no hard and fast line between the two bodies of doctrine. A function depends on the way the machine is made. And many provinces of modern research, such as those depending on changes of general form in response to external agents, combine morphology and physiology. For convenience of research, physiology is often divided into *biochemistry* and *biophysics*. But this distinction can scarcely be regarded as a scientific one, since in all vital processes both chemical and physical factors intervene. It is true that some of the problems of the biochemist consist in the elucidation of the chemical nature of vital products, and might be looked upon as the chemical side of morphology; but the methods of investigation distinguish them from those of the organic chemist.

Animal and Plant.—There is no real or fundamental difference between the animal and plant organism. Great as may appear to be the external differences between a dog and a tree, when we proceed to examine the physiological factors of which their life is made up, we find that the elementary processes are essentially alike. The most striking contrast, that of movement, does not exist in the simplest members of the two kingdoms. While certain plants, such as algae and bacteria, are motile in some stages, certain polyps and ascidians become fixed in the later periods of their life. Other instances might be given. The difference between the net result of the chemical changes occurring in the green plants and those occurring in animals is due to the presence in the former of the green pigment, chlorophyll, and does not show itself in fungi. By the aid of chlorophyll, the energy of the sun's light is used to build up the carbon dioxide, formed in the combustion of food by all cells, into sugar and oxygen. These again become available as sources of energy to living matter. In this connexion, it may be noted that the work of Willstätter and Stoll has made it practically certain that carbon dioxide and water become attached in some way to the chlorophyll particles, a molecular rearrangement takes place with addition of energy when light is absorbed, a peroxide of formaldehyde is produced, and this is then decomposed into gaseous oxygen and formaldehyde by the agency of an enzyme (catalase). From formaldehyde the higher sugars are readily produced by polymerization. The precise chemistry of the reactions is not yet clear—it may be that formic acid and hydrogen peroxide result from the action of water on the formaldehyde peroxide. In this case, catalase splits up hydrogen peroxide into water and oxygen, while the formic acid is reduced by light (absorbed by chlorophyll) to formaldehyde. However this may be, the final result of the process is that, in the light, green plants take up carbon dioxide and give off oxygen. In the dark, they behave like animals, giving off carbon dioxide by combustion. Such combustion, of course, is actually proceeding in the light also, although obscured by the opposite phenomenon.

Vitalism.—Some discussion, not very profitable as far as physiology is concerned, has taken place as to the existence of

a form of energy, or, as held by some, of a kind of directing agency peculiar to living beings. The aim of all physiological experimentation is to express vital processes in terms of physical and chemical laws. We call this "explaining" them. The methods used, moreover, are those of physics and chemistry. Owing to the complexity of the phenomena, we have to be content in many cases with expression in terms of simpler physiological laws, leaving the further analysis of these laws to the future. As Claude Bernard pointed out, the laws of physics and chemistry manifest their action in systems of a special kind, differing from those familiar to workers in the former sciences, so that the separation of a biological group is quite justified. At the same time, there is intimate connexion and overlapping, a process subject to continual increase.

As to the existence of a peculiar form of "vital" energy, it is to be admitted that we have no direct method of measuring the energy contained in a given mass of carbon and oxygen, although we know that a definite quantity of work can be obtained by allowing them to combine. Thus, the energy of living things cannot be looked upon as altogether peculiar. Indeed, measurements of any form of energy are usually made by converting them into other forms. The first law of energetics tells us that this is permissible. The striking fact that any organism behaves as a unified and coördinated set of activities has led to the assumption of a directing agency of some kind. We shall see later that notable progress has been made in the explanation of the factors responsible for many aspects of this integration.

The position of consciousness in physiological processes is by no means clear. While it may be held that the province of physiology is to investigate what can be made out experimentally in the nervous centres, it does not seem impossible that consciousness may ultimately fall into place as one of the functions of nervous tissue.

Relation to Physical Chemistry.—One of the most striking aspects of the development of modern physiology is the important part played by considerations derived from physical chemistry. The osmotic pressure of solutions, the action of the various inorganic ions arising from the electrolytic dissociation of salts, acids and bases, especially the hydrogen ion, and the maintenance of the neutrality necessary to the normal function of the cell, together with the properties of matter in the colloidal state and of heterogeneous systems in general may be mentioned. The absorption of substances at the surfaces of contact of phases that do not mix has been found to explain many otherwise puzzling facts, and is doubtless a prominent factor in the formation of the membrane covering the surface of cells in general and regulating the passage of dissolved substances into and out of the cell protoplasm.

This is perhaps the most appropriate place to refer to the relation of vital processes to the second law of energetics. In one of its aspects, this law points out how the transformation of heat energy into other forms is limited, owing to our conditions of existence being at a temperature so far above absolute zero. The properties which we recognize as "vital" are especially manifested during the change of one form of energy into another. In this process, it is of much importance from the point of view of economy that the free chemical energy of our food should not be "degraded" to heat before utilization in muscular work, and so on. Similarly, the energy of the sun's light must be converted to chemical energy by the green plant as directly as possible, without passing through the stage of heat. Accordingly we find that arrangements are made to ensure that loss from such causes shall be as small as possible.

Nature of Protoplasm.—As usually seen in such organisms as the amoeba or the leucocytes of the blood, protoplasm exhibits the properties of a liquid. It contains numerous particles in Brownian movement, a fact which shows the absence of obstacles holding them in place. This liquid, however, is itself a colloidal solution and can be seen under special modes of illumination to be closely packed with extremely minute particles. Under some states of activity, as in dividing cells or when electrically stimulated, this "hydrosol," to use Graham's word, becomes a

"gel," in which the particles have joined together to form minute closed chambers in which liquid is confined, the whole mass then possessing the properties of a solid. This process occurs when a warm solution of gelatin solidifies on cooling. It will be clear that if protoplasm contains many-formed solid structures, as in highly differentiated cells, together with comparatively little free water, it may be scarcely possible to detect its liquid nature. However difficult it may be to conceive the way in which different chemical processes can occur at different places in a liquid, this must be the case, and suggestions have been made as to the temporary formation of separating membranes or other less mechanical means of isolation. The notion of protoplasm as a giant molecule in the chemical sense, with numerous side-chains of a variety of composition capable of reacting together, is held by but few physiologists at the present time. A view of this kind is contained in the theory of "biogens," to which reference will be made later.

The *cell-membrane* is evidently formed by surface condensation of some constituents of protoplasm. In ordinary circumstances, it is impermeable to salts, to glucose and to amino-acids. But since these substances must obtain access to the interior as foods at certain times, it is clear that the membrane must become more permeable when required. The constituents of the membrane being deposited at the surface owing to their properties of reducing surface energy, the actual chemical composition of this layer must be of a complex nature. It is probably, for the most part, an intimate mixture of fatty substances with watery proteins. These may form two kinds of colloidal systems—minute droplets of fat may be surrounded by a continuous solution of protein, like islands in a sea, or they may themselves run together and enclose droplets of protein, similar to the land surrounding a number of lakes or ponds. The properties of these two systems, as regards the passage across them of materials, will not be identical. Thus, rabbits cannot get through the system of islands, fish can do so; while the reverse will be the case with the other kind of system. Familiar instances of the contrast are well known in the forms of cream and butter. The former is a suspension of droplets of oil in a watery solution, the latter consists of droplets of the watery solution in a continuous medium of fat. The investigations of Clowes have shown how, by the action of electrolytes, particularly of calcium ions, one system can be changed into the other. A difficulty is sometimes felt as to how a membrane which refuses passage to sugar allows visible solid particles to pass through, as can be seen in the amoeba and leucocytes. The explanation lies in the manner in which a needle can be dropped through a soap film without breaking the film. A continuous film of the membrane is formed over the point as it enters and again over the eye-end as it leaves. Thus the membrane is never actually broken. A further point to be remembered in the modifications of the cell-membrane is that, being formed of materials present in the cell, it is an integral part of this and must change in correspondence with functional changes in the cell itself. Thus it appears that it becomes more permeable in states of activity, as in the contraction of muscle and in the secretory process of gland cells. If the surrounding medium itself contains substances that lower surface tension, these no doubt contribute to the structure of the membrane. Such is usually the case in the cells making up the animal body, less so in the plant.

Certain substances, proteins and others, become more or less solidified in the process of concentration in surface films, as Ramsden has shown. This fact must also play a part in the formation of the cell-membrane.

As to the *chemical nature* of protoplasm itself, it seems very questionable whether it can be regarded as a uniform chemical compound. Although proteins take a large share, various other substances, such as the complex fats known as *lipoids* or *lipines*, are important components. All the constituents are interconnected in a highly heterogeneous system, partly chemical, partly physical, of many phases and intersected by semi-permeable membranes forming and disappearing at intervals.

Attention may here be called to the special properties of the *carbon atom* as forming the basis of the chemical changes associated with living matter. Compounds of carbon do not naturally react otherwise than slowly. They are, therefore, subject to ready modification in this respect by the agency of the catalysts called "enzymes." Owing to the capacity of carbon atoms to unite together in long chains or rings of a relatively stable nature, along with the possession of four valencies capable of union with four different groups, we have the possibility of the production of highly complex large molecules. Another property of importance in the carriage of energy is the power of combining with elements of opposite character, such as hydrogen and oxygen. The hydrocarbons give up energy on oxidation, while the carbon dioxide can be reduced and built up again by addition of energy to form stores of potential energy for future use.

Although such large complex molecules are of great importance, the view of the essential nature of protoplasm as a further growth

of the chemical molecule, the "biogen" hypothesis, cannot be accepted. According to this view, food material is combined chemically, as a side chain, with a giant molecule, while certain other side chains consist of oxygen. In oxidation, to give energy, combination takes place between these side chains. It follows from such a view that oxygen must be stored up in living cells in an "intra-molecular" form. Now, investigations from many points of view have failed to obtain evidence of the existence of such reserve oxygen. There is no proof that an organism possesses any store of oxygen beyond that contained in the lungs or dissolved in the fluids. It appears that the mechanism of living matter is more analogous to that of a petrol engine, in which the fuel does not form part of the structure previously to its combustion, but that this combustion takes place in intimate relation with the moving parts and that it is owing to the special arrangement of these that the chemical energy of the fuel is converted into the mechanical energy of motion. It is true that such cells as those of muscle and secreting glands have been shown to prepare during rest a store of some kind of system possessing potential energy, ready for use on stimulation to activity. But the process of conversion of this system to one of lower energy content is not associated with the consumption of oxygen or evolution of carbon dioxide. Thus the system is not comparable with a "biogen" and may probably be rather of a physical than a chemical nature. The energy necessary to form it is obtained by the combustion of some food material, apparently carbohydrate, with the giving off of carbon dioxide and involving some loss in the form of heat. The state of activity and the actual combustion process are therefore separate phenomena and the conception of giant molecules throws no light on their nature. It is rather as if the combustion of the fuel in our petrol engine were used, through some mechanism, to pump water to a high level, from which the energy could be obtained by allowing it to run down when required.

The Nucleus of the Cell.—Although this component is present in all the more highly organized cells, it is obvious that it cannot be essential in this actual form. Bacteria, for example, do not appear to possess a nucleus, although the materials out of which it is made are probably present distributed through the cell. If, as Morley Roberts suggests, the nucleus is a store of enzymes, the tools of the cell, it might be supposed that, in the absence of the nucleus, these tools are not kept in a special receptacle. Although statements have been made that oxidative processes are especially carried out by the nucleus, the evidence is unconvincing.

The nucleus undergoes a remarkable series of changes in the course of the subdivision of one cell into two daughter cells. This process, known as "karyokinesis" or "mitosis," exhibits a complex play of directed or polar forces. The inheritance of the Mendelian characters of organisms is conveyed by the nuclear constituents. The general characters are held by some to be transmitted by the cytoplasm. But, although it is difficult to believe that the cytoplasm plays no part, it would appear that if all the general characters are thus carried, those of the male parent would be practically unrepresented, since the spermatozoa are almost devoid of cytoplasm. Further evidence is needed.

When a nucleated cell is cut into two parts, one alone containing the nucleus, this part can continue to exist, whereas the other part degenerates and dies. Thus, the nucleus is essential to the life and growth of a cell in those cases where it has become a specially differentiated part. The fact is particularly manifest in the case of the cells called *neurones*, which make up the nervous system. Here there is a very long fine fibre arising from a nucleated mass. This is a "nerve-fibre," and if cut away from its nucleated origin, it degenerates and ceases to be able to conduct nerve impulses.

Nutrition.—During 1910-21 much attention was given to problems of the phenomena of nutrition, necessitated in great part by the conditions brought about by the World War of 1914-8. Since the chief use of food is to supply energy and energy cannot be created, it must always be kept in mind that a given amount of food can only provide a certain definite quantity of energy. For convenience of measurement, this is expressed in terms of heat units, calories. An adequate diet must have a certain minimal calorie value, or energy value, differing according to work done, age, weight, etc. Whatever else may be necessary, and whatever may be the composition of the diet, this energy value must be provided. The fact must not be allowed to be obscured by recent work on the importance of special constituents, such as "vitamins" or the presence of particular chemical compounds.

Further, food is obviously required in the growing organism to make new tissue and in the adult to replace wear and tear. Although the actual quantity needed for these purposes is not great, it is clear that it must contain all the chemical elements making up the constituents of the new tissues. There are moreover certain rather complex chemical compounds that must

supplied, since the higher animals are unable to make them. Nitrogen is needed for the production of proteins, and is in fact taken in food in this latter form, although afterwards broken down into its constituent amino-acids in the process of digestion. A certain minimal amount of protein food is therefore a necessity. When burned, protein gives energy, and might therefore be used for this purpose, if taken in sufficient quantity. But such a proceeding would be costly and wasteful. Accordingly, we make up the greater part of the energy value of our food by non-nitrogenous compounds, fats and carbo-hydrates. The latter appear also to be necessary for proper assimilation of protein. Some discussion has taken place as to the actual necessity of fat, since it has been shown that in the organism fat can be made from carbo-hydrate. Careful experiments indicate that it is not indispensable. Its chief value, physiologically, lies in its high energy value, greatly owing to the very small amount of water contained in the forms used for food.

On account of the fact that the nitrogen of protein appears to be needed only or mainly for the construction of new body substance, there has been a tendency to reduce the consumption of protein. This is advocated chiefly on grounds of economy. Although excessive consumption of this or any food is physiologically harmful, there does not appear to be satisfactory reason for supposing that protein is particularly injurious. On the other hand, it has been stated that a consumption of protein in considerable excess of the minimum requirement is of advantage in conferring greater resistance to infection. Apart from the ill effects of any diet deficient in energy value as a whole, no satisfactory evidence has been brought in support of the statement. It may be said that if any reasonable diet of animal or vegetable structures, including fruit, be taken, it will only be necessary to take account of its energy value. Sufficient proteins and vitamins will be automatically obtained. The dictum of the present writer "Take care of the calories, the proteins will take care of themselves" may indeed be read "Take care of the calories, other things will take care of themselves."

It may be useful to give the composition of the diet put forward by the Royal Society Food Committee as a standard for a man of 70 kilos weight, doing moderate work:

Protein	70 grammes =	280 calories
Fat	90 grammes =	810 "
Carbo-hydrate	550 grammes =	2200 "
		Total 3290 calories

It is understood that this refers to that part of the diet actually utilized and does not include undigested components.

In addition to the above-mentioned, there are certain things which, although they do not contribute to the energy value of a diet, are nevertheless indispensable for the proper working of the cell machinery and the utilization of the material presented to it. Water is needed for the carrying on of chemical reactions and for the conveyance of products from place to place. The colloidal systems of the cell are maintained and modified by salts, especially those of sodium, potassium and calcium. This adjustment, as Macallum has pointed out, is doubtless an inheritance from adaptation to the composition of the ocean in early geologic times, from whose inhabitants the present land animals are descended. We find, moreover, certain metals, such as iron, manganese, copper and magnesium, present in small amount in living organisms. We know that iron is a constituent of the red pigment of the blood corpuscles, by which oxygen is supplied to the tissues. In certain invertebrate organisms, it is replaced by copper. Magnesium is a corresponding element in the green pigment of plants, chlorophyll, without which life would come to an end owing to the using up of the oxygen of the atmosphere. Iron and manganese are of importance in the mechanism by which food is burned and its energy obtained. Certain moulds will not develop completely without zinc. It is more than likely that many other metals present in traces are more than mere accidental contaminations. Calcium, as we have already seen, plays an important part in the adjustment of colloidal systems. Potassium, although we know it to be indispensable, presents difficulties. Zwaardemaker maintains

that its importance rests in its radio-activity, but other workers have not been able to replace it by other radio-active elements. Sodium salts, at the present time, serve chiefly to make up the osmotic pressure of the blood and tissue fluids. The occurrence of iodine in the internal secretion of the thyroid gland must not be overlooked.

Vitamins.—Not the least interesting of those constituents of a diet whose presence is absolutely necessary, although small quantities suffice, are the accessory food factors called by this name. The name "vitamine" was originally given owing to a mistaken view of their chemical nature. But, since it has come into general use and is conveniently short, objection to it may be removed, as Drummond has pointed out, by omitting the final "e" and using it merely as a name, without implication of chemical structure.

So far as known at present, they are three in number, distinguished by the addition of the letters A, B and C. Vitamin-A is commonly found in association with certain fats, such as butter and cod-liver oil, but it is also present in fresh vegetables. It is essential to normal growth and maintenance and its absence appears to be responsible for rickets in children. Vitamin-B is found in the germ of seeds, such as wheat and rice, but it is widely spread. Its absence from polished rice results in beri-beri, when this food material is the only one taken. Vitamin-C is required for normal nutrition, although the precise manner in which it acts is unknown. In its absence, the disease known as scurvy makes its appearance. This vitamin is much less stable than the preceding ones and is found only, to any notable extent, in fresh fruit and vegetables. Although all of these factors occur in animal products, they are present there owing to the vegetable food taken by animals. Their ultimate source is the plant, since animals are unable to make them. It is more particularly Vitamin-C that is defective in animal products. Fresh meat contains it in a very small amount. Owing to the minute quantities that are physiologically sufficient and are alone accessible for investigation, their chemical nature is as yet unknown. They do not undergo change in the course of their activity, but are excreted or destroyed more or less rapidly. Thus, their activity appears to be of a catalytic nature, but nothing very definite can be stated at present.

The normal growth of plants is also dependent on similar accessory factors. The "bios" of yeast, and Allen's work on diatoms may be referred to here. Bacteria, also, require in many cases special materials, such as haemoglobin, or particular amino-acids, for satisfactory culture.

It should be noted that certain products formed by organs in the body itself have powerful effects on the chemical changes of growth and nutrition. To these "internal secretions" or "hormones" reference will be made below.

Anabolism and Catabolism.—It was held at one time that all food materials, previous to further utilization, must be built up into the actual constitution of complex protoplasmic molecules such as "biogens." And that the activities of organs typified by muscular contraction and glandular secretion consisted in the breaking down of such complex chemical individuals. The former process was spoken of as "anabolism" or "assimilation," the latter as "catabolism" or "dissimilation." More recent work has led to a somewhat different point of view, as already indicated above. It appears that glucose, for example, is burned without becoming a part of the protoplasmic structure and, although the energy thus available is used for the storing up of potential energy in some complex system, to be used up in subsequent contraction or secretion, this system may not necessarily be of a purely chemical nature. If the anabolic and catabolic processes are opposite chemical reactions in the sense of the building up and breaking down of the same compounds, it is natural to suppose that while the former process is taking place the latter is *ipso facto* decreased. Hence, the view that the nerves producing a reduction of activity (inhibition) are anabolic in action. Investigation, however, has failed to give confirmation of such a view of the nature of the inhibitory process.

Allied to the above problem is that of the existence of nerves influencing the growth or repair of tissues. Although definite statements cannot yet be made, evidence of any such influence, apart from changes in blood supply, is inconclusive.

Enzymes.—These catalytic agents are of great importance in the chemical changes of living organisms. It is generally recognized that they are colloidal and that the reactions accelerated by them

take place on their surfaces. Thus, a preliminary absorption of the components of a reaction occurs preparatory to the actual chemical change. Whether this increased concentration or close approximation by molecular forces is in itself sufficient to account for the effects or whether there is an intermediate compound formed between the material of the surface of the enzyme and the substances to be acted upon is not yet clear. No such compound has been prepared, but its existence may be so brief as to elude detection. It is evident, however, that the chemical nature of the surface of the enzyme particles may be held responsible for the variety of limited and special activities met with amongst these substances. At the same time, it is not to be forgotten that the physical properties of this surface depend on its chemical nature. In this connexion the views of Langmuir on the orientation of molecules in surface layers may be referred to. In regions of molecular forces, no valid distinction can be drawn between chemical and physical forces.

Much discussion has taken place as to whether enzymes have synthetic as well as hydrolytic powers. In the majority of cases we are dealing with undoubted reversible reactions, which attain an equilibrium position other than complete change in either direction. But the two opposite reactions which determine the equilibrium point proceed naturally at a very slow rate. If an enzyme were to accelerate one of these without the other, the equilibrium position would consist in practically complete change in one direction. If this position as reached under the action of an enzyme is anywhere but at the extreme in one or the other sense, it follows that the enzyme has quickened *both* the hydrolytic and the synthetic reactions. Many cases of this kind are now known. The actual position of the equilibrium depends on the concentration of water in the system. Thus, in order that the synthetic activity may be preponderant, arrangements are required by which this concentration of free water may be decreased. This may be effected in the cell by colloidal imbibition by absorption on surfaces, or by osmotic action. If the products of synthesis are rapidly removed either by being deposited in an insoluble form, as for example starch or glycogen are, or by being carried away in the blood stream, the synthetic process may be continuous, since equilibrium is not reached.

Oxidation.—As is well known, the living organism is able to burn food materials, such as glucose, fat and so on, which are only oxidized with such extreme slowness by atmospheric oxygen that combustion appears to be absent in many cases. The mechanism by which oxidation is effected in the organism consists in making use by enzymes of products of oxidation of certain materials which are attacked by atmospheric oxygen. Although details of the mechanism are not altogether clear, the main facts are as follows. When a substance, such as an unsaturated fat or lecithin, is oxidized by oxygen as it exists in the air, it is said to undergo *autoxidation*. In this process, *pari passu* with the formation of the ordinary oxide, which of course affords available energy, a peroxide is formed by the aid of this energy. It appears also from Mrs. Onslow's work that the autoxidation may be hastened by an enzyme, thus affording a larger supply of the peroxide. But while a peroxide in itself has greater oxidizing power than oxygen in the molecular state has, or in other words its oxidation potential is higher, this potential is not sufficiently high to attack glucose or lactic acid. If, however, a small amount of a ferrous salt be added, a catalytic separation of oxygen in an "active" state occurs and such refractory materials as lactic acid are then oxidized (Fenton's reaction). Whether active oxygen is atomic or whether it is in the process of changing its valency, as Ramsay used to teach, is uncertain. The important fact is that we find in living organisms an enzyme, "peroxidase," capable of acting on peroxides in the same way as the iron in Fenton's reaction. Indeed, it seems likely that either iron or manganese is the responsible constituent of the enzyme.

Oxidation or reduction may also be brought about by substances which remove hydrogen from water, thus leaving reactive oxygen. As Hopkins has shown, a sulphur group (S-S) may take up hydrogen to form HS-SH, while this compound in its turn may hand on hydrogen to an "acceptor," and so reduce it.

Integration.—Organisms behave as coördinated systems, not as collections of separate cells. There must accordingly be means of inter-communication between all parts. In the animal, the most obvious of these is the nervous system, which makes its appearance at a very early stage of evolution. It may be compared to the telephone system of a city, by which any part can be connected up with any other. This comparison is in many ways an instructive one. Any one subscriber can be put into communication with any other and his line is a "final common path" for messages from various sources. Thus, the nerve supplying any particular muscle is made use of in many various movements, since it can be connected up in the brain with different nerves conveying their respective messages from the sense-organs.

Details of researches on the activities of the central nervous system are beyond the scope of this article. In general it may be said that the conception of a series of alternative parallel arcs at different levels in the hierarchy has shown itself an illuminating one. When the higher arcs come into use, those of lower levels fall into disuse and become relatively resistant to the passage of impulses. These lower arcs still remain potentially active and when the higher parts are removed gradually become functional again, to

a greater or less degree. In some cases, their activity is kept in check by the higher arcs and liable to become more or less excessive when the influence of these is removed. Such "release" phenomena play an important part in the manifestations of the nerve centres, especially in abnormal states.

• Pavlov's method of "conditioned reflexes," by which physiological, objective, research on the cerebral cortex can be made, has already led to many valuable results. The part played by inhibitory processes has been shown to be a very important one.

As animals grow in size and complexity, some system analogous to that of mechanical transport by roads or railways becomes necessary. Oxygen has to be conveyed to all parts of the body from the place in which it is obtained from the air. The carbon dioxide and other products of chemical change require removal for the purpose of elimination by the organs devoted to this purpose. Food has to be taken from the alimentary canal to other organs in which it is burned or used for repair. As is well known, it is by means of the blood flowing in a voluminous network of tubes that this aspect of integration is effected. Thus, materials in quantity are carried from one organ to another. As regards oxygen and carbon dioxide, further remarks will be found below.

Much attention has naturally been given to the pump, known as the heart, which serves to keep the blood flowing through the vascular system. The most important recent work is that of Starling embodied in the *Law of the Heart*. It was found that all the responses of this organ to the demands of the circulation, apart from the effects of nervous reflexes upon it, could be explained on the basis of a certain property common to all muscle. This property, which was clearly brought out by the work of A. V. Hill, is that the magnitude of any given contractile effort depends on the length of the fibres when the contraction begins. Hence, the more blood enters the heart during rest the greater is the force expelling it in the next following beat. The property of muscle referred to shows that the source of the contractile stress must be sought in certain surfaces arranged longitudinally or in the direction of the pull exerted. (For recent work on the capillaries, see SHOCK.)

But the system of mechanical transport of a town serves to carry letters in addition to materials for actual use as such. The chemical substance of these letters is not utilized, but they contain messages by which a supply of something or other is ordered to be sent from its source to a place where it is wanted. The so-called "internal secretions," "chemical messengers" or "hormones" correspond to the letters of the postal system. These are produced in some organ and carried by the blood to other situations in which they set various processes into activity. Thus, for example, adrenaline is sent out from the suprarenal glands into the blood. Reaching the liver, it causes a supply of glucose to be set free and supplied to the body generally. It has, of course, other actions as well. We know many of these chemical messengers at the present time. They are formed in the thyroid, pituitary, pancreas, sex-glands and so on. In one or two cases their chemical nature is known, but for the most part this is not yet the case. It seems very probable that every tissue in the organism has its influence on other tissues. In the culture of tissues under the microscope,—a method of investigation which has now reached much perfection,—it is found that the growth and differentiation of one kind of tissue is greatly influenced by the presence of other tissues.

In the higher plants, this effect of one part upon another is well shown by the inhibitory effect of the apical growing tip upon the growth of other buds. The work of Child suggests that this effect is of the nature of a protoplasmic transmission of some influence rather than the diffusion of an actual inhibiting hormone, as was supposed by the previous workers.

Carriage of Oxygen and Carbon Dioxide.—Although it has been known for some time that it is the haemoglobin of the red corpuscles that carries oxygen from the lungs to the rest of the body, there is still much to learn about the mode in which this gas is attached to the haemoglobin. There are some puzzling phenomena, not the least of which is the fact that we know of no other chemical compound that takes up and gives off oxygen in a way similar to that of haemoglobin. In particular, one which combines with oxygen in proportion to the pressure of the gas up to a saturation point which appears, in the case of the blood pigment, to correspond with one molecule of oxygen to each molecule of haemoglobin. Much valuable work has been done on the relationship referred to, especially by Barcroft and his coadjutors, more especially on the way in which it is affected by changes in the conditions present in the blood and tissues. The problem is one of paramount importance in the life of the higher organisms.

The problem of the carriage of carbon dioxide is in a more disputed state. While some hold that it is effected by the proteins of the blood acting as acids and driving off carbon dioxide from sodium bicarbonate when the tension of carbon dioxide is lowered, others hold that this gas is carried by haemoglobin in the same way in which oxygen is carried. The decision necessitates difficult measurements and is still uncertain.

Regulation of Reaction.—Whether the sodium bicarbonate of the blood acts as a carrier of carbon dioxide or not, there is no doubt that it has an important function in preserving the neutrality of the blood. As would be expected from the fact that the various chem-

ical processes take place with the intervention of colloids, they are very sensitive to changes in hydrogen-ion concentration. This is particularly the case with enzymes. The blood contains sodium bicarbonate, which in itself has an alkaline reaction, owing to hydrolytic dissociation, together with carbon dioxide which forms an acid when dissolved in water. The reaction or hydrogen-ion concentration of the blood is thus controlled by the relative proportion of these two constituents, and is normally at a very slight degree of alkalinity. If acid is formed anywhere and passes into the blood, it combines with part of the bicarbonate, driving off carbon dioxide and thus raising the acidity. But the respiratory centre is enormously sensitive to such a rise and removes carbon dioxide by increased ventilation of the lungs until it is reduced to a level corresponding to the reduction of the bicarbonate. It has been held by some that the proteins assist in the process, but it is very doubtful whether this effect is more than very trifling, if present at all.

Excretion of Waste Products.—The removal of one of the chief of these, carbon dioxide, has been discussed. The most important of the non-volatile products is urea, most of which is derived from the ammonia of the amino-acids absorbed in excess of the amount required for repair. There are a number of others in small quantity, some nitrogenous, others not, which, although not really of a toxic nature, are of no value. These are all non-colloidal and therefore pass freely through the wall of the blood-vessels. The colloidal constituents of the blood, mainly proteins, and the blood corpuscles do not normally pass through, except in a few places, such as the liver, where the membrane is incomplete. Owing to the pressure produced by the heart, there is a tendency to a continuous filtration through the walls of the blood-vessels of a solution containing all the diffusible constituents of the blood. But the proteins of the blood do not diffuse and, since they are such as to have an osmotic pressure of about 30 to 40 mm. of mercury, they may be regarded as attracting water with a force of this magnitude. Unless the blood pressure exceeds this value, therefore, no filtration occurs, and where it is below, reabsorption takes place. The pressure in the arterioles and beginning of the capillaries exceeds the osmotic pressure of the colloids, whereas it is lower than this in the rest of the circulation. In the greater part of the body, the filtered fluid escaping reabsorption is known as lymph. In the kidneys, the glomeruli are arranged so as to filter a large amount of fluid, which is the first stage of the production of urine. This process as described would suffice to remove all the waste products. But if the whole filtrate were allowed to escape from the kidney, not only would a large quantity of water be lost, but with it such valuable substances as salts and food materials, sugar and amino-acids. What we actually find is that the filtrate is caused to pass along a system of tubules, in the course of which a large part of the water, together with useful solutes, is reabsorbed, while the useless waste products are left in more concentrated solution. It has been shown by Cushman that if it be supposed that the fluid absorbed has invariably the normal composition and concentration of the blood plasma as regards diffusible substances, but without the waste products, all the phenomena of renal function can readily be explained.

It would appear that the chief function of the plasma proteins is to confer a colloidal osmotic pressure, so that excessive filtration is avoided. In the absence of such an osmotic pressure, not only would a large amount of liquid be exuded into the tissues, but there would be no force available for its reabsorption and a dropsical state would result. In fact, this is what happens when a simple salt solution is introduced into the circulation (see SHOCK).

On the basis of the theory given above, it will be noted that the energy for the actual production of the glomerular filtrate is provided by the blood pressure, that is, by the contraction of the heart. On the other hand, the cells lining the tubules have to do work against osmotic forces, since they remove a dilute solution from a more concentrated one. This work increases as the fluid passing along the tubules becomes more concentrated. It must be provided by some cellular mechanism analogous to a pump, requiring the provision of energy to actuate it. The investigations of Tamura indicate that this consumption of energy per unit time is unchanged, whatever may be the amount of urine produced by the kidney. Hence, the more concentrated the glomerular filtrate, the less fluid is reabsorbed from it.

Stimulation and Environment.—The capacity of an organism to respond in an appropriate manner to changes in its environment clearly depends on its power of properly appreciating such changes. Hence, the more richly endowed is an organism with means by which it is enabled to be affected by the various forms of energy impinging upon it, the better it is fitted to profit, both materially and intellectually, by knowledge of the outer world.

In order to understand the essential character of a receptor or sense-organ, as we call the structures by which such information is obtained, one or two fundamental facts brought out more clearly by investigations in recent years have to be considered.

Receptor organs are connected to the brain each by its own set of nerve fibres. These fibres proceed to special regions in the brain, and it appears that whatever the manner in which impulses are set in motion along the fibres, the process in them is the same. So that the fact that the sensations aroused are in one case light, in another taste, and so on, depends on the terminus in the brain. And from

whatever source this terminal "centre" is aroused to action, the effect in consciousness is the same. If, for example, the trunk of a nerve of taste is stimulated, either electrically, mechanically, or chemically, a sensation of taste is evoked. A further fact that has been made clear by Adrian's experiments is that the nerve-impulse itself cannot be made other than of a definite magnitude by varying the strength of the stimulus. In any particular state of the nerve, if it is excited at all, the maximum response possible is obtained. In the case of the heart muscle, this fact has long been known and was given the name of the "law of all-or-nothing" by its discoverer, Bowditch. This law has now been shown to hold for voluntary muscle and for nerve. It is true that the work of Adrian was done on motor nerves, but no difference between these and sensory fibres in other respects has been shown to exist, and there is some direct evidence that the law holds in the case of the optic nerve. It appears then that the impulses travelling along nerves are the same in all cases and that their various results are due merely to the structures in which the fibres end. The statement applies also to efferent nerves, in that there is no difference in nature between nerves which have excitatory and those which have inhibitory action on the structures in which they end. The difference, as Langley pointed out, is in the manner in which their final connexion is made. The question is indeed an aspect of Müller's law of specific sense-energies. The name is not very explicit, but the law states that the excitation, however produced, of each nerve of special sense gives rise to its own peculiar sensation.

We see then that what is required in a receptor organ is that some process shall be set going in it on the incidence of a particular form of external energy, and that this process shall be such as to stimulate the nerve fibres arising from the organ. It is clear that receptors of a different kind are necessary in the cases of light, sound, heat, touch and so on. While the nerve fibre itself can be stimulated by pressure or by heat of sufficient intensity, it is insensitive to light or sound waves, and even in the former case its sensibility to direct action is far too small for the appreciation of the fine degrees of touch, temperature, etc., which is required. The state of affairs is well shown by the properties of the heat and cold spots on the skin. There are distinct receptors for temperatures above that of the skin and below it. The former give a sensation of heat, the latter of cold, and a temperature that feels warm to a heat spot has no effect on a cold spot and *vice versa*. Thus each is especially sensitive to its own appropriate stimulus. If an electrical stimulus or a temperature high enough to affect the nerve fibres directly is used, the sensation from a heat spot is one of warmth, the opposite from a cold spot. But the intensity of stimulus necessary is much greater than that required in the stimulus for which the particular organ is adjusted. The paradoxical fact that a temperature of 45°C. feels hot to a heat spot and cold to a cold spot is readily explained on the basis of stimulation of the nerves of the organ and the operation of the law of specific sensation. Although it is not easy to prove the fact directly, there is every reason to believe that, at all events in the higher senses, each separate nerve fibre has its own special connexion in the brain and its own individual sensation.

It was remarked above that, so far as evidence goes, all nerve impulses are alike. There is, however, a possibility, pointed out by Keith Lucas, that these impulses may, within the limits imposed by the refractory period, follow one another at different intervals of time. Then, if a particular nerve fibre is connected with two or more neurones in the centre, and if the properties of transmission or refractory periods of these "synapses" differ, it may happen that a rapid series of impulses may be able to pass one and not the others. In this way, a single nerve fibre may serve more than one purpose.

For further details the following books may be consulted: Starling, *Principles of Human Physiology* (3rd ed., London, 1920); Bayliss, *Introduction to General Physiology* (London, 1919); Bayliss, *Principles of General Physiology* (3rd ed., London, 1920). In the latter, references will be found in the "bibliography" to special monographs and original papers. (W. M. B.)

PICKERING, EDWARD CHARLES (1846-1919), American physicist and astronomer (see 21.582), died in Cambridge, Mass., Feb. 3 1919.

PINERO, SIR ARTHUR WING (1855-), English dramatist (see 21.625). Amongst his later plays are *The Mind the Painter* (1912); *The Big Drum* (1915); *Mr. Livermore's Dream* (1917); *The Freaks* (1918); and a wordless play, *Monica's Blue Boy* with accompanying music by Frederic Cowen.

PIRRIE, WILLIAM JAMES, 1ST VISCOUNT (1847-), British shipbuilder and engineer, was born at Quebec May 31 1847, and educated at the Belfast Royal Academic Institution. In 1862 he entered the shipbuilding firm of Messrs. Harland & Wolff of Belfast, and by his industry and talent he rose to be its head, becoming partner in 1874 and later chairman. His success was particularly associated with the building by his firm of the White Star Line steamships, the first of the line, the "Oceanic," being launched in 1870. From 1896 to 1897 he was

Lord Mayor of Belfast, and in 1898 the freedom of the city was conferred upon him. In 1906 he was raised to the peerage as Baron Pirrie, and was for a time comptroller of the household of the Lord Lieutenant of Ireland, and pro-chancellor of Queen's University, Belfast. Towards the close of the World War, in 1918, he was made controller-general of merchant shipping. In 1921, on the King's visit to Belfast to inaugurate the new Parliament of Northern Ireland, he was created a viscount.

PISSARRO, LUCIEN (1863—), Anglo-French painter and engraver, was born in Paris on Feb. 20 1863, the son of the painter Camille Pissarro (see 21.652). He studied art under his father, and at the suggestion of Auguste Lepère took up wood engraving. In 1891 he came to England, and there began his studies in typography. In 1894 he started the Eragny Press and published a series of books, using until 1903 the Vale type designed by Charles Ricketts and afterwards the Brook type designed by himself. The initial letters, borders and illustrations engraved on wood were throughout mainly from his own designs, and sometimes show very skilful and refined use of colour and gold. Among the most notable productions of his press are *L'Histoire de Soliman Ben-Daoud* (1907); *Le Livre de Jade* (1911) and *La Charrue d'Erable* (1912), with illustrations engraved in colour from drawings by Camille Pissarro, one of his son's few essays in reproductive engraving. He also produced a considerable number of isolated woodcuts. As a painter, he uses the "spectral palette" of the impressionists, and works in a high key. He early devoted himself to the study of subtle gradations and variations in colour, and adopted a pointillist technique, afterwards modified into a broader method of handling, with more emphasis on design. His work is almost entirely English landscape, notable recent examples being "Coldharbour, Teatime" and "Crockhurst Lane, Coldharbour." He became a member of the New English Art Club, was a member of the Camden Town Group, and was the principal founder of the Monarro Group. He became a naturalized British subject in 1916. He is represented in the Tate Gallery, and in the art galleries of Leeds and Manchester.

PISTOL (see 21.654).—During recent years the automatic pistol has been gradually perfected and adapted to replace the revolver as a military side arm, despite the fact that there are many who maintain that the revolver is the more dependable weapon. The automatic pistol, like all complicated mechanisms, occasionally malfunctions, usually due to a defective magazine or cartridge. This disadvantage is, however, offset by the fact that from the pistol about three times the number of shots per minute may be fired as from a revolver; its magazines are changed instantly, thus giving sustained fire while loaded magazines are at hand. This gives a great advantage to the user of a properly working pistol, as a revolver is often useless at close quarters, such as obtained in trench raids, after its six shots have been fired. In such positions the volume of fire from a group of pistols is much greater than that from an equal number of revolvers even if a pistol is occasionally disabled by a jam.

Owing to its simpler mechanism, the revolver is more reliable for civilian self-defence where more than two or three shots are seldom required; the weapon then being unused and often neglected for long periods. The revolver is also considered superior to the automatic pistol in safety. In the latter, the loaded cartridge automatically inserted in the chamber after each shot is liable to be forgotten and left there when the magazine is taken out. To prevent accidental discharge from this source, some of the newer models have a "magazine safety," which prevents the pistol from being fired when the magazine is out. In addition, a "grip safety," which prevents discharge unless the rear part of the grip is pressed in at the same time the trigger is pulled; and a safety catch, which locks the slide and hammer, are often used. Recent models of revolvers show no improvements of note, and it is probable that with the attention now being given to the design of the automatic pistol, that weapon will eventually be made as reliable, safe, and quick to get into action as a good revolver.

In European armies previous to the World War, the pistol was used almost exclusively as an officer's side arm. Their weapons were of small calibre, ranging from 7.63 mm. to 9 mm., and lacked stopping power. During the war the use of the pistol and revolver was extended to include many branches of the service not armed with rifles, particularly by the United States, British and German armies. The large calibre weapons of the former armies gave them a great advantage in pistol-fighting, and their use confirmed previous opinions that a large calibre heavy bullet of short range and low velocity is more effective in a pistol than a high velocity, small calibre bullet.

Automatic pistols have now been adopted by the armies of the United States, Belgium, Spain, Italy, Denmark, Portugal, Switzerland, Germany and Austria. The British navy has adopted the Webley automatic pistol. In the table on page 107, details are given.

Colt Automatic Pistol.—The Colt automatic pistol, calibre .45 (fig. 1), was adopted by the U. S. army in 1911. This pistol differs radically from older Colt models in that it has a sloping handle, grip safety (1), spiral mainspring (2), an improved method of locking the barrel and breech, also an improved slide action and magazine catch (3). The magazine (4) has a capacity of seven cartridges. The ammunition for this pistol has a muzzle velocity of 800 f.s. with a 230-grain bullet. The striking energy is 329 ft. lb., which gives a penetration of 6 in. of white pine at 25 yards. The pistol is capable of great rapidity of fire, 21 shots having been fired in 12 seconds beginning with the pistol empty.

The action of the .45-calibre pistol, assuming that it is cocked and ready to fire, is as follows: When the trigger (5) is pulled, the sear (6) is released, and the hammer (7), actuated by the mainspring (2), goes forward and strikes the firing-pin (8), which transmits the blow to the primer of the cartridge. The pressure of the gases generated in the barrel (9) by the explosion of the powder in the cartridge, is exerted in a forward direction against the bullet, and in a rearward direction through the cartridge case against the face of the slide (10), driving the slide and the barrel to the rear together. The link (11), one end of which is fixed to the frame and the other to the barrel, causes a downward pull on the barrel when it recoils, which disengages the barrel lugs (12) from the slide, and the barrel is then stopped in its lowest position. The slide continues to move to the rear, opening the breech, and cocks the hammer (7) which moves the hammer strut (13) downward, compressing the mainspring (2). The sear (6) actuated by the sear spring (14) engages in the notch on the hammer (7). Extracting and ejecting of the empty shell are accomplished and the recoil spring (15) compressed until the slide reaches its rearmost position, when another cartridge is raised into loading position. The cartridge is forced into the chamber of the barrel by the return movement of the slide under pressure of the recoil spring. The slide during its forward motion encounters the rear extension of the barrel and forces the barrel forward; the rear end of the barrel swings upward on the link (11) to the normal firing position. When the slide and barrel reach their forward position they are positively locked together by the locking lugs on the barrel and their joint forward movement is arrested by the barrel lug encountering the pin on the slide stop (16). The pistol is again ready for firing.

The inertia of the slide augmented by that of the barrel is so much greater than the inertia of the bullet that the latter has been driven from the muzzle of the barrel with its maximum velocity before the slide and the barrel have recoiled to the point where the barrel commences its unlocking movement. This construction of opening of the breech of the barrel until after the bullet has left the muzzle and therefore practically prevents the escape of powder gases to the rear after the breech has been opened.

PISTOL

This factor of safety is further increased by the tension of the recoil spring and mainspring, both of which oppose the rearward movement of the slide.

The U.S. army uses the pistol as the standard side arm. All officers and enlisted men in the cavalry, field artillery, tank corps, signal corps and machine-gun companies, and most of the officers and non-commissioned officers in other branches are armed with it.

In the shortage of pistols incident to the World War, Colt and Smith & Wesson revolvers of the same calibre, chambered for the same rimless cartridges, were used. The use of the rimless cartridge in the revolver was accomplished by providing semicircular loading clips which hold three cartridges by lugs which fit in the cannellure of the cartridge. The ejection is accomplished by this means. The clips make the loading much faster.

The Colt automatic pistol is also made in .22-in., .25-in., .32-in., .380-in., and .38-in. calibre military models.

Browning Automatic Pistol.—The new model Browning automatic pistol (fig. 2) made by the Fabrique Nationale, Belgium, is representative of modern automatic pistols of pocket size. This pistol is made in 7.65-mm. (.32) and 9-mm. (.380) calibres. A military model of 9-mm. calibre is also made which is used by the Belgian army. The pistol shown is of the "blow back" type, the barrel (17) being locked to the frame (18), the slide (19) being free to recoil. On pulling the trigger (20) and pressing in the grip safety (21), the sear (22) revolves on its axis and releases the firing-pin (23), which actuated by the coiled firing-pin spring (24), moves forward and fires the cartridge. The inertia of the slide assisted by the recoil spring (25) delays the rearward motion of the slide until the bullet passes through the barrel. The slide then recoils, compresses the recoil spring and the firing-pin spring and ejects the empty cartridge case. When the notch in the under side of the firing-pin passes over the sear nose, the latter actuated by the sear spring (26) rises and holds the firing-pin in a cocked position. When the effect of the recoil is overcome, the slide moves forward in the usual manner feeding a loaded cartridge in the chamber. The magazine (27) is released by the catch (28), and when the magazine is taken out the magazine safety (29) locks the sear and prevents discharge.

Webley Automatic Pistol.—The Webley, the only automatic pistol manufactured in Great Britain, is made in .25, .32, .380, .38 and .455 calibres (fig. 3). The latter size, which fires a 270-grain bullet, has been adopted by the British navy. The action is unique in that a flat recoil spring (30), situated in a recess in the right grip and compressed by the recoil lever (31), absorbs the recoil and returns the slide (32) to firing position. In the larger calibres, the barrel (33) is locked to the slide at the moment of firing and these parts recoil together a short distance; the barrel then rises upon diagonal cam-shaped lugs which unlock the slide and permit it to travel back alone. During this rearward movement, the empty case is ejected and the hammer (34) cocked. The forward motion of the slide then feeds a cartridge from the magazine in the chamber in the usual manner. The trigger (35) is connected with the sear (not shown) by means of a trigger auxiliary lever (36) and sear tail (37). The magazine is situated in the handle and holds eight cartridges.

The .38 calibre Webley pistol is used by the London metropolitan police. A .25 calibre hammerless model has recently been brought out which has a spiral recoil spring parallel to the barrel in a recess in the slide.

Savage Automatic Pistol.—This pistol (fig. 4), which is extensively used in the United States, and has been adopted by the army and navy of Portugal, is made in .32 and .380 calibres. The magazine

for the former holds ten cartridges; that for the latter, nine. The 1917 model differs from the previous one in that an outside cocking lever is added, and the shape of the grip changed to facilitate aiming. There is no grip safety or magazine safety on this pistol, the cocking lever indicating whether it is in firing position. The barrel and breech are locked at the moment of firing by means of a locking lug on top of the barrel which engages with an angular locking slot in the bolt and makes it necessary for the barrel to rotate about one-eighth of a turn to the right to unlock. The resistance of the bullet to rotation in the rifling tends to twist the barrel to the left and prevents the bolt from turning it to the right until the bullet leaves the barrel. The momentum of the recoil then forces the bolt back, the angular slot rotates the barrel and the rest of the cycle of operations is performed much as in the pistols already explained.

Remington Automatic Pistol.—The newest (1920) model automatic pistol to be placed on the market is the Remington .380 calibre automatic (fig. 5). In general this weapon follows the usual lines of automatic pistols. The breech closure is of the positively locked recoil-operated type. The recoil spring is held in a sleeve concentric with the barrel, and the magazine, which holds seven cartridges, is in the stock. The weapon has three safety devices: a grip safety, a slide safety catch which also indicates whether the weapon is cocked or not, and a magazine safety which prevents the pistol from being fired when the magazine is withdrawn. The recoil when a shot is fired forces a movable breech block in the slide backward for about $\frac{1}{4}$ in., and into contact with recesses in the frame, this movement accomplishes primary extraction and transmits an initial thrust to the slide which is free to move backward against the recoil spring. This movement of the slide through a camming action lifts the breech block out of engagement with the frame and carries the breech back, cocking an internal hammer and ejecting the empty case. The chamber is reloaded in the usual manner on the return stroke. There are no screws in this pistol and it may be disassembled without tools other than the firing-pin.

European Pistols.—The German Parabellum (Luger) and Mauser pistols have been little changed from those described in previous editions of the *E.B.* The Parabellum 9-mm. calibre is the standard German military arm, but during the shortage, incident to the World War, they used a great variety of weapons, the principal ones being the Mauser, Bayard, Browning, Borchardt, Bergman, Pieper, Sauer and Dreyse. There were reported to be 28 different models of pistols and revolvers in use in the German army. The Parabellum is also used by the Swiss and Bulgarian armies.

A drum or "snail" magazine (fig. 6) holding 32 cartridges was applied to the Luger pistol during the war. This magazine consists of a straight section similar to the ordinary pistol magazine with a round enclosed drum at the bottom. There are two springs, one functioning as an ordinary magazine spring, and a flat drum spring resembling a clock spring which with its casing fills the drum except for space for a single row of cartridges around the edge. There is a lever and catch on the outside for winding this spring and a rotating feeding lever inside which fits in the cartridge space between the inner casing and drum. The magazine spring is compressed between the last cartridge and this lever, which being revolved by the drum spring pushes the magazine spring and cartridges around the drum as the pistol is fired. When the drum is empty the magazine spring functions in the usual manner. This style of magazine was also applied

to the Bergman pistol gun and the Mondragon semi-automatic rifle. It destroys the balance of an arm and is of doubtful value. The Bayard automatic pistol 9-mm. calibre is used in the Danish army. The commercial pistols of this make in .32 and .380 calibres

are the smallest automatics of these calibres on the market. The Victoria is the smallest .25 calibre. The Mannlicher is used by the Austrian army.

The Campo-Giro automatic pistol 9-mm. calibre was adopted by Spain in 1914. The principal merit claimed for it is that a special recoil check lessens the shock and permits more accurate firing.

the entire city. The mayor continued to appoint the heads of departments (safety, works, health, charities, supplies, property, water, treasury). The comptroller also was elected as formerly by popular vote. The expanding of public business in the city and county, exceeding the capacity of the city hall and the court-house, led to the erection by joint action of a new City-County Building, a fine structure of nine stories. The county in 1920 was completing a twin tunnel under Mount Washington to connect the southern hill district with the city by a high level bridge over the Monongahela river, which will bring that district within 15 minutes' transit of the centre of the city. In 1919 the taxable valuation of Pittsburgh was \$1,113,667,425, and the tax rate in 1921 was, for the city, 20 mills on land, 14 mills on buildings and 8.50 mills for school purposes. In 1919 a bond issue of \$22,500,000 was voted by the people for subway, boulevards, playgrounds, bridges, parks, etc.

The value of Pittsburgh's products in 1919 was \$602,582,300, compared to \$246,604,000 in 1914. In 1920 it held sixth place in bank clearings (\$8,982,887,399) and first place in *per capita* deposits (total \$817,013,249) and in the manufactured products—iron, steel, glass, electrical machinery, steel cars, tin-plate, air brakes, fire-brick, white lead, pickles and preserves, corks and aluminium. The production of pig iron in the city in 1919 was 31,015,364 tons and in the surrounding district 7,440,746 more, a total of 38,456,110 tons. Metal and metal products were valued at \$324,261,900; chemical products \$2,045,800; clay, glass and stone products \$4,345,500; clothing manufacture \$7,122,800; slaughtering and meat-packing \$21,134,700; confectionery \$6,490,500; leather and rubber products \$5,589,700; cork-cutting \$4,016,500; oil-well supplies \$3,678,100. The production of radium in 1920 (18 gr.) probably exceeded that of the rest of the world. The sum of \$970,072,700 was invested in 2,580 industrial plants, mills, foundries and furnaces, in which were employed 221,621 men, with a daily pay-roll (1920) exceeding \$2,500,000. The annual tonnage of Pittsburgh is 2½ times the combined tonnage of New York, London and Hamburg. As a port of

(H. O'L.)

PITTSBURGH (see 21,678) had, according to the U.S. census of 1920, a pop. of 588,193. The increase over 1910 was 54,288 or 10.2%. After the 1920 census was taken the township of Chartiers, with a pop. of 5,000, was annexed, petitions were filed for the annexation of the borough of Homestead with a pop. of 20,452, and a movement was on foot for the merger of the boroughs of Wilkensburg (24,403), Ingram (4,000), Grafton (5,934) and others. Within the metropolitan district of a 10-m. radius, but outside the city limits proper, there was a further population equal in number to that within the municipality itself. In Allegheny county, of which Pittsburgh is the county seat and business centre, there were in 1920 1,184,832 persons, 13.6% of the total pop. of Pennsylvania.

The sesqui-centennial of Pittsburgh, elaborately observed in 1908, marked the beginning of a new period of corporate, educational, social and material development. By legislative enactment (1911) the former Common and Select Councils gave way to a small council of nine members, elected by general vote of

entry, the value of imports in 1918 was \$6,391,960. The city's contribution to the Liberty and Victory loans was \$625,429,600, to the Red Cross \$10,194,765, and to the seven relief agencies \$13,909,000, making a total of \$649,533,365.

In 1911 the Legislature adopted a new school code for the entire commonwealth, coming into operation Nov. 11 1911. Under this code a Board of Education, consisting of 15 members appointed by the Common Pleas judges, took control. Separate school districts were abolished; a new city superintendent, with associate superintendents, was appointed; the scattered and unrelated school agencies were consolidated; new high schools and junior high schools established and buildings erected, such as the Schenley high school, built in 1916 at a cost of \$1,500,000 and accommodating 2,000 students. New ward schools of modern construction were established. The teachers numbered in 1920 2,015 in 133 grade schools and 494 in 11 high schools, and the enrolment of pupils in grades was 74,654 and in high schools 12,169. There were in evening grades 198 teachers and 6,245 pupils, and in evening high schools 148 teachers and 5,000 pupils. The public-school system was supplemented by non-public schools which had in 1920 650 teachers and 33,000 pupils. In addition to the high schools there were a number of academy schools, 77 in all, on private foundations. The development of education during the decade was notable. The Holy

became Duquesne University, and in 1920 had 2,129 students, including department of law, 86 students, and evening school of accounts and finance, 1,120 students. The Carnegie Institute in the decade increased the extent of its service to the community; its central library, with 464,313 volumes, had 8 branches, 16 stations, 128 school stations, 10 club stations and 8 playground stations, with a circulation of 1,363,365 books; both the scientific museum and the art department added greatly to their collections; in the school of technology the enrolment grew from 2,102 students in 1909 to 4,982 students in 1920, including those in the departments of science and engineering, arts, industries and the Margaret Morrison school for women. The university of Pittsburgh, established in 1908 by assembling the scattered departments of what was the Western University of Pennsylvania, and taking over 43 ac. near the Carnegie Institute for a campus, grew rapidly in its new location, and in 1920 numbered 4,979 students. In the same year there were in the city 227 social, health, religious and welfare agencies.

After careful study of playground systems a bond issue of \$800,000 was voted (1919) to initiate a constructive development of parks and playgrounds at public expense. Another civic improvement was the plan that a permanent committee of citizens should be engaged in the solving of the housing problem, and that the chamber of commerce, coöperating with the state, should employ a director in charge of the Americanization programme in which the public schools and corporations coöperate. The Society for the Improvement of the Poor, constructed and opened (1921) the Wayfaring hotel to accommodate 500 men. The 20 hospitals, modern in construction and equipment, with 4,500 beds, included special hospitals for children, eye and ear, maternity, tuberculosis, and contagious diseases. The Magee hospital, established by legacy of \$3,500,000 under will of the late C. L. Magee, by agreement the maternity hospital of the university of Pittsburgh, is perhaps the most modern and complete maternity hospital in America. (S. B. Mc.)

PIUS X. [GIUSEPPE SARTO] (1835-1914), Pope (see 21.690), died Aug. 20 1914. Although the pontificate of Pius X. lasted only 11 years (Aug. 4 1903-Aug. 20 1914), it has been said that his work for the Church, reconstructive and reformative, surpassed that of any of his predecessors since the days of Sixtus V., who died in 1590. In the defence of the Faith, his condemnation of the 65 propositions of Modernism in 1907 will rank in Catholic theology as a parallel to the condemnation of the 68 propositions of Molinism by Innocent XI. in 1637 or the 101 propositions of Jansenism condemned by Clement XI. in 1713. The activity of the pontificate may be judged by the fact that its output of papal Bulls and greater official papal documents (counting only those published) exceeded 3,322. These bear upon undertakings and reforms of the first importance—the codification of canon law; the protection of the liberty of the Conclave by the abolition of the *Exclusiva*; the simplification and security of the conditions of marriage by the *Ne Temere* legislation; the restoration of the Rota as the supreme Court of Appeal; the regulation of the triennial or quinquennial visits of bishops to Rome; the legislation as to Church music; and the decree as to First Communion, and the encouragement of international eucharistic congresses; the reform of the Roman breviary; the founding of the biblical institute for the work of Scriptural research; the regulation of studies in the seminaries; the creation of the commission for the great work of editing the true text of the Vulgate; the reconstruction of the official machinery of the Roman Curia; the transfer of the English-speaking countries from the propaganda or missionary régime to the normal government of the Church. To these may be added in the domain of discipline the unflinching vindication by Pius X. of the Church's right to depose delinquent bishops, carried out even at the cost of rupture of diplomatic relations with France; an apostolic visitation rigorously carried out through the dioceses of Italy, resulting in four bishops being caused to resign on account of neglect or inefficiency; a further regulation by which no one can be proposed for a bishopric unless his promotion receives the visa of the Holy Office, which means that his past life has been free from ecclesiastical censure or reproach.

The well-known personal characteristics of Pius X. were his piety, charity, deep humility, simplicity, pastoral zeal, combined with great charm of manner to all who approached him. For war he had nothing but horror and it was the shock of the outbreak of the World War that hastened his death. It is said that one of his last acts was to refuse the request of the Austrian Emperor to bless his soldiers, saying, "I do not bless war: I bless peace." (J. Mo.)

PIUS XI. [ACHILLE RATTI], elected Pope on Feb. 6 1922 at the Conclave following the death of Benedict XV., was born May 30 1857, at Desio, near Milan. He came of a middle-class Italian family, his father, Francesco Ratti, being manager of a textile factory. Achille was the third of six children, and was educated for the priesthood at the seminary of Milan and the Lombard College in Rome, becoming deacon in 1877 and priest in 1879. Devoting himself to study, he took doctorates in philosophy, theology and canon law in Rome, and in 1882 became a teacher in the major seminary at Milan. In 1888 he was chosen one of the college of doctors of the Ambrosiana Library in Milan, where he worked assiduously, becoming librarian in 1907, and attaining so high a reputation as a scholar that in 1910 he was also appointed by Pius X. vice-prefect of the Vatican Library. He was prefect of the Vatican Library from 1913 to 1918, and in this capacity was made a monsignor. During the war years his exceptional gifts as a diplomatist impressed themselves on Benedict XV., who, in the spring of 1918, sent him as Papal Nuncio to Poland, where his success led to still further distinctions. In June 1919 he was created Archbishop of Lepanto, in April 1921 Archbishop of Milan, and in June 1921 cardinal.

PLENER, ERNST, FREIHERR VON (1841-), Austrian statesman, was born on Oct. 18 1841 at Eger in Bohemia, the son of the excellent Austrian statesman Ignaz von Plener (1810-1908). He began his diplomatic career in 1865, and served in the Paris and London embassies until 1873. In the latter year he was elected by the Chamber of Commerce of his native place to the Chamber of Deputies of the Reichsrat, where he was soon reckoned among the most conspicuous members of the Constitutional party. In the Taaffe period (1879-93) he was one of the leaders, and from 1888 the acknowledged head of the German-Liberals in their struggles against the Slav-Conservative majority in the Chamber. Consequently he represented Germanism on the nationalities question, but was not averse to concessions compatible with the maintenance throughout the whole monarchy of the position due to the German Austrians. He sought to compromise the quarrel between Germans and Czechs, and the so-called "points" of 1890, a summary of the bases for a German-Czech understanding, were essentially his work. In the Windischgrätz Coalition Ministry (1893-95), Plener took over the portfolio of Finance. Soon after his retirement from the Finance Ministry, Plener was appointed president of the Supreme Audit Department (*Oberste Rechnungshof*). He became a member of the Upper House in 1900.

Plener wrote a series of economic and political works, among others *Die Englische Fabrikgesetzgebung* (1871); *Englische Baugesellschaften* (1873). His speeches were published by his friends in 1911. He himself published *Erinnerungen* (3 vols., 1911-21). (A. F. Pr.)

PLUMER, HERBERT CHARLES ONSLOW PLUMER, 1ST BARON (1857-), British field marshal, was born March 18 1857, and entered the army in 1876. He served on the Red Sea Littoral in 1884, and in 1896 commanded a mounted regiment in the Matabele Campaign, for which he was promoted brevet lieutenant-colonel. Before the outbreak of the South African War in 1899 he was sent out to the Cape on special service, and he raised the Rhodesian field force, which he commanded during the early months of the contest. He assisted in the relief of Mafeking, and was promoted colonel, appointed A.D.C. to the Queen, and given the C.B. In the later stages he was constantly in command of a column or a group of columns, and he was promoted major-general on the conclusion of hostilities. He commanded a brigade at home from 1902-4 and was then appointed quartermaster-general at headquarters, a position which he vacated at the end of 1905; shortly afterwards he was appointed commander of the 5th Division. He was promoted lieutenant-general in 1908 and in 1911 was placed in charge of the Northern Command.

In May 1915 Sir Herbert Plumer was selected to lead the II. Army on the western front, and shortly afterwards he was promoted general. His army was not very actively engaged during the remainder of 1915, nor yet in 1916, in which year he was given the G.C.M.G. for his services. But on June 7 1917

Plumer gained a signal victory at Messines on the opening of the Flanders offensive, for which he was given the G.C.B. Three months later he assumed charge of the operations east of Ypres, which had been making slow progress, and his dispositions were for a time highly successful; but the recovery of the whole of the high ground could not be accomplished owing to the lateness of the season. Then, just as the Flanders offensive concluded, he was in Nov. selected to take charge of the British troops that were being sent to the basin of the Po after the Italian defeat at Caporetto. He commanded them until March, but he was then summoned back to Flanders to resume leadership of the II. Army just before the great German offensive started. During the later stages of the hostile effort his troops were forced back some miles, but they succeeded in checking the enemy. Then, when the general advance of the Allies began in Aug., his army took a very prominent part in the operations by which Belgian Flanders was recovered from the invaders. For his services in the war he was raised to the peerage as Baron Plumer of Messines and of Bilton, was promoted field marshal, and received a grant of £30,000. He subsequently commanded the British forces on the Rhine for a short time, and in June 1919 went out to Malta as governor and commander-in-chief.

PLUNKETT, SIR HORACE CURZON (1854–), Irish politician (see 21.857), after his retirement in 1907 from the vice-presidency of the Irish Agricultural Department, took no prominent part in politics till the crucial year 1914. In Feb. of that year, when suggestions for an agreed settlement of the Irish difficulty were pouring in from all sides, he came out, in a long letter to *The Times*, with a scheme of his own, under which Ulster should accept the Home Rule bill, but should have a right to secede after a term of years, while the Ulster Volunteers should become a Territorial Force, partly as an ultimate safeguard of the Ulster Unionists. Hitherto he had been regarded as a moderate Unionist, but this suggestion rendered him suspect in Ulster eyes, and the suspicion was confirmed when he published in the third week of July a pamphlet entitled *The Better Way: an Appeal to Ulster not to Desert Ireland*, in which he announced his conversion to Home Rule and appealed to Ulster to give Home Rule a chance, re-stating the arguments of his previous letter, and suggesting a conference of Irishmen on the bill. This was his attempt to avert civil war; but the situation was revolutionized by the outbreak of the World War. Once again, in 1917, a year after the Dublin rebellion, he took the lead in an honest attempt to solve the Irish question. When Mr. Lloyd George set up a comprehensive convention of Irishmen to consider the matter, and report their conclusions, there was great difficulty in finding a suitable chairman; but the first meeting unanimously chose Sir Horace for the post. He was himself sanguine, and worked at his task with singular devotion; but the absence of Sinn Féin from the gathering, the impossibility of reconciling the views of the Ulstermen and the southern Unionists, and the occurrence of a number of tragic events in Ireland, prevented the adoption of any report with colourable unanimity. In 1920–1 he was a prominent advocate of "Dominion Home Rule" (see IRELAND: History).

PODMORE, FRANK (1856–1910), English psychologist, was born at Elstree, Herts, Feb. 5 1856. Educated at Haileybury and Pembroke College, Oxford, he became interested in psychical research, and was closely associated with Edmund Gurney and F. W. H. Myers in the telepathic and psychical investigations described in their joint publication *Phantasms of the Living* (1886). He also published *Apparitions and Thought Transference* (1894); *Studies in Psychical Research* (1897); *Modern Spiritualism* (1902) and other works on the subject. He was found drowned near Malvern Aug. 15 1910.

POINCARÉ, JULES HENRI (1854–1912), French physicist (see 21.892), was born at Nancy April 29 1854, and educated at the *lycée* in that town. As a boy he served in an ambulance corps during the Franco-Prussian War of 1870, and later passed with distinction through the *École Polytechnique* in mining, becoming a mining engineer, but soon abandoning practical work for teaching, first at Caen and later in the university of Paris. He

won the King of Sweden's open prize for a mathematical treatise in 1889, and in 1908 was elected to the *Académie Française*. He was a voluminous writer on his own special subjects. Some details of his contributions to science are given in 19.859, 25.786 and 26.947. He died in Paris July 17 1912.

POINCARÉ, LUCIEN (1862–1920), French physicist (see 21.892), was born at Bar-le-Duc July 22 1862. After a distinguished academic career he became in succession inspector-general of physical science in 1902, director of secondary education at the Ministry of Public Instruction in 1910, director of higher education in 1914 and rector of the *Académie de Paris* in 1917. In that capacity he received President Wilson at the Sorbonne on the occasion of his visit to Paris for the Peace Conference. He died in Paris March 9 1920.

POINCARÉ, RAYMOND (1860–), French statesman and writer (see 21.892). After the fall of the Sarrien Ministry in 1906 M. Poincaré ceased for some years to take an active part in politics. On Dec. 9 1909 he was made a member of the French Academy. In 1911 he was invited to join the Monis Ministry, but refused. His opportunity came at the beginning of 1912, and on Jan. 13 he became head of what was popularly known as the "great" or "national" Ministry, in which he also held the portfolio of Foreign Affairs. As Prime Minister Poincaré aimed at safeguarding the interests of France abroad, especially against the menace of the Triple Alliance, and at strengthening her at home by firm government and the restoration of social discipline. In this he was helped by the revival of a strong national feeling in France, provoked by the international crisis of 1911. The fact that he was a Lorrainer prejudiced public opinion in his favour, and his popularity was increased by his foreign policy—especially the successful establishment of the French protectorate over Morocco and the conclusion of the naval agreement with Russia. In Aug. 1912 Poincaré went to St. Petersburg to confer with the Tsar and his ministers about the Franco-Russian Alliance and the new developments of the Eastern question, a visit which countered the somewhat depressing effect in France of the meeting of the German and Russian Emperors at Baltic Port on July 4. The Balkan Wars, and Poincaré's attitude towards the problem raised by them, greatly increased his prestige; he declared on Dec. 4 to the Foreign Affairs Committee of the Chamber that he was determined to secure respect for the economic and political interests of France, not only in the Balkan Peninsula, but in the Ottoman Empire generally, and especially in Syria.

At the beginning of 1913 he became a candidate for the presidency. This action excited strong personal as well as political feeling, and his election was hotly contested, the second and third ballots showing a majority for his most serious competitor, M. Pams. On appeal to the National Assembly, however, he was ultimately elected by a majority of 187 votes over M. Pams, his inauguration taking place on Feb. 18 amid great demonstrations of popular enthusiasm. Two days later he showed that he intended to exercise the right of the President to address Parliament direct—a right which had fallen into desuetude—by sending a message to the Chambers, in which he stated that it was his function as President "to be a guide and adviser for public opinion in times of crisis" and "to seek to make a rational choice between conflicting interests." His activities as President were still directed to strengthening the internal and external position of France. In June 1913, after inspecting the fleet at Toulon, he paid a State visit to England (24–27), during which he enlarged on the necessity of the perpetual association of the two nations "for the progress of civilization and the maintenance of the peace of the world." In the autumn he made a motor tour of the south of France,—being greeted everywhere with popular acclamation, the bands playing the irredentist march "Sambre et Meuse,"—and attended the army manoeuvres at Toulouse. His State visit to Spain followed in October.

The President's activity and enormous popularity roused the anger of the Opposition parties, and the Radical-Socialist congress at Pau, on Oct. 17, passed a resolution condemning "the aspirations of personal policy." This had no effect, how-

ever, on public opinion, and Poincaré's popularity was undiminished during the months immediately preceding the outbreak of the World War. On the very eve of the war, immediately after the rising of the Chambers on July 15 1914, Poincaré set out on a State visit to Russia and the Scandinavian countries, arriving at Kronstadt on July 20. His visit to Sweden was, however, interrupted by the serious news from France, and on the 29th he was back in Paris. He now made a personal appeal to King George V. to use his influence in favour of peace, while the Ministry asked for the armed intervention of Great Britain. After the outbreak of war his activities were mainly directed to stirring up the patriotic spirit of the people, as in his messages to the Chambers of Aug. 4 1914 and Aug. 5 1915, or his speech on July 14 1915 on the occasion of the transference of the remains of Rouget de Lisle, the composer of the "Marseillaise," to the Invalides. On Oct. 4 1914 he also visited the French head-quarters.

After the conclusion of the Armistice Poincaré made a tour in Alsace and Lorraine, his official entrance into Metz taking place on Dec. 4 1918. On Jan. 18 1919 he opened the Peace Conference in Paris with a short speech, in which he emphasized "justice" as the guiding principle of the victorious Allies. His term of office expired on the following Feb. 18. He subsequently accepted the presidency of the Reparations Commission, which he resigned in May 1920 as a protest against what he considered to be the undue leniency shown to Germany. This became the text of a violent press campaign which he carried on, against the policy of the Supreme Council in general and of Mr. Lloyd George in particular (see *FRANCE: History*). During 1920 and 1921 it was Poincaré's influence that was mainly dictating the aggressiveness of French feeling in international politics; and during the latter part of Briand's premiership, culminating in Briand's visit to the United States for the Washington Conference at the end of 1921, it was Poincaré who was fomenting the criticism that French interests were being undermined. The result was seen when, in the midst of the Cannes Conference in Jan. 1922, the proposal for an Anglo-French treaty of defence led to Briand's hasty return to Paris to answer interpellations with regard to his policy in the Chamber, and to his sudden resignation on Jan. 13 without facing discussion on a vote of confidence. Poincaré was at once entrusted by President Millerand with the formation of a new Cabinet, which he completed on Jan. 25, and French policy under his premiership was now given a definitely Nationalist orientation.

Poincaré's published works include *Du droit de suite dans la propriété mobilière* (1883); *Idees contemporaines* (1906); *Questions et figures politiques* (1907).

See Henry Girard, *Raymond Poincaré* (1913); *Raymond Poincaré, a sketch* (1914); *Larousse Mensuel*, No. 158 (1920).

POISON GAS WARFARE.—The use of poisonous gases in warfare, as started during the World War, was only made possible by modern progress in chemistry. From a purely objective point of view, and apart from all ethical considerations, it should be observed that fighting-men have, at some time or other, adopted any means of making war, however ruthless. Poisoned weapons and poisoned wells are as old as history. The ancient Greeks indeed used sulphur fumes, and the Byzantines "Greek fire"; and in mediaeval sieges carcasses of dead animals were thrown over the defences from mangonels, in order that their putrefaction might spread disease. Underground warfare in all times has been marked by attempts to drive the enemy from his galleries with smoke and suffocating fumes. The usages of chivalry, while prescribing courtesy to prisoners, imposed no limit on means of destroying life. Only in the 18th century, when war in western Europe became a very formal affair, did a tendency appear to set such limits. Both Louis XIV. and Louis XV. declined the use of "infernal liquids" offered to them by chemists. Later the tendency to impose moral restrictions became more definite. Lord Bunsen's proposal for the use of suffocating smoke-clouds at the siege of Sebastopol was rejected by the British Cabinet. In 1854 at Châlons experiments with suffocating shells were made, but before Napoleon III., who

stopped the trials and declared that such barbarous means of destruction would never be employed by the French army because they were against the "law of nations." In the S. African War of 1899-1902, the Boers thought they were justified in complaining of the injurious effects of the gases given off by the British high-explosive shells. It was only indirectly that the Hague Convention limited the use of gas. It forbade, by Art. 23 (e), the use of weapons calculated to cause unnecessary suffering; "poison or poisoned weapons" by Art. 23 (d). A separate declaration had, some years before (July 29 1899), forbidden the use of projectiles whose "sole object it was (*qui ont pour but unique*) to spread deleterious or asphyxiating gases." The method which actually arose in the World War—that of a fixed apparatus which propels liquid gas in a jet—had apparently not then been generally foreseen. If it had been, the use of poisonous gases would, no doubt, have been more explicitly forbidden.

It is one of the ironies of history that the first great war after the Hague Convention should have witnessed its entire uselessness to limit human suffering. Gases of a nature to cause lifelong injury, liquid fire, molten metal, burning phosphorus—all were employed with a prodigality limited only by the inventive powers of the combatants.

There was, of course, no objection to the use of gases and substances of the lachrymator class. The object of these is to cause temporary incapacity by violent smarting of the eyes, sneezing or retching, while the effect passes off when the subject is removed from the radius of action of the gas. Probably the earliest example of this class is the Chinese "Stinkpot"; and it is interesting to note that as the Chinese were before the Western nations in the use of gunpowder, so they also were in this early form of what, in the World War, came to be known as "Chemical Warfare," a term which in itself is really too wide for "gas warfare," since chemistry enters into explosives also.

At the time of the Russo-Japanese War the subject of lachrymators was taken up by the Japanese, and later by the British War Office. It was also investigated by the French for police purposes. The British experiments covered a wide range of compounds based mainly on iodine, bromine and picric acid. The chief subjects of inquiry were effectiveness, keeping qualities and the effect of the liquid on the container. Nothing very highly effective was found, and it appeared that most of the liquids required a container of lead, glass or porcelain, on account of their action on steel or cast iron. The experiments were dropped some years before the World War, probably because, in the kind of warfare that was then anticipated, it did not appear that there would be much use for lachrymators.

In 1913 the question was submitted again to the British War Office. The Hague Convention was always kept in view, and it was considered that the term "deleterious" applied only to gases which caused permanent harm. As one chemist pointed out, poisons were prohibited by the convention, but disagreeable fumes were not. A few experiments were made with compounds of the lachrymator class in shells, and the question remained alive until in Sept. 1914, after the outbreak of war, it was decided not to use chemical shell of this type for the British army or navy.

Quite early in the World War stories began to be current on each side of the employment of gas shells by the other. In Dec. 1914, upon a semi-official suggestion from the British G.H.Q. in France, a section of the War Office, working with Sir William Ramsay's Chemical Sub-Committee of the Royal Society, took the question up again. By this time trench warfare was fairly established and the armies of both sides were immobilized in trenches, facing each other in some places at a distance of only a few yards. All possible means of trench fighting had to be considered, and among other things it was thought that, if a sufficient number of lachrymating grenades could be thrown from the British front trenches into those of the enemy, he might be forced to evacuate them temporarily, or might at least have his fighting power considerably reduced by being forced to the constant use of a protective mask.

In Jan. 1915, an idio-acetate compound was brought forward which caused such smarting of the eyes that it was impossible to

remain in its neighbourhood. By that time catapults were available which could throw a 2-lb. projectile 200 yards, a distance which brought the enemy's trenches within range in many parts of the line. A tinned iron cylindrical grenade was therefore designed to hold 2 lb. of liquid, which by means of a 5-second time-fuze and detonator was made to burst and distribute the lachrymator in a fine spray. The British War Office and G.H.Q. approved of this grenade, and the manufacture was put in hand. At the same time many other substances were considered, mostly lachrymators and sternutators. Some of these compounds appeared to be very effective under experimental conditions, but were not so in the field.

While these modest tentatives were proceeding, always within the limits laid down by the Convention and the Declaration, the first German gas attack took place on the Ypres front on April 22 1915. This immediately altered the whole situation, as it was obvious that in using chlorine—an asphyxiant—the Germans had transgressed, if not the letter of the Declaration and the Convention, certainly their spirit. Accounts of the sufferings of those who had been exposed without protection to this new form of attack roused great indignation, but its effectiveness could not be ignored, and after a few days it was decided by the British authorities that preparations at least must be made to reply to the German gas offensive in the same manner. The section of the War Office that had been dealing with lachrymating grenades was instructed to take up the question, and with the aid of two or three chemists of the highest standing a small council was formed which sat continuously to discuss ways and means and consulted all the most prominent chemists and manufacturers. It soon became evident that the Germans had employed chlorine gas discharged under pressure from cylinders placed in the front line of trenches. A rapid review of all possible means of reply showed that chlorine was the easiest gas to begin with, but the position of Great Britain in this matter was very different from that of Germany. For the ordinary processes of the dye industry, the Germans produced in peace-time very large quantities of liquid chlorine. In England only one or two firms produced it, and that in very small quantities. Moreover, the available containers for transport of the chlorine were not only very few but were much too bulky and heavy for use in the field. The problem therefore was twofold: first, to install apparatus for an enormously increased supply of liquid chlorine, and secondly to design and manufacture suitable cylinders or dischargers for its use in the field. In both cases many initial difficulties were encountered, which were overcome in due course, and on Sept. 25 1915, at Loos, the first British gas attack with chlorine took place.

Meanwhile a very large range of possible gases had been passed under review with the object of discovering substitutes for chlorine. Obviously the thing to aim at was something which was more directly lethal than chlorine, and at the same time would cause less suffering by its effects. It was also realized from the first that the discharge of gas from the front trenches necessitated waiting for suitable weather conditions, which was very inconvenient for the arrangement of tactical operations; and it appeared to be necessary to release the gas in the enemy's lines, so as to be independent of wind, which could best be done from gun shells or trench-mortar bombs. The principle was approved and a new class of problems had now to be faced.

Effects of Gases.—At this point it will be convenient to consider the effects produced by different varieties of gases, and the methods of employing them.

When considered from the point of view of their physiological effect, war gases may be classed in two main divisions, (a) Lethal, and (b) Irritant. The lethals fall under the two heads: those whose action is instantaneous or practically so (specific), and those whose action is more or less delayed, and is generally of an asphyxiating character.

A gas is classed as immediately fatal when death follows exposure for a period of two minutes to a certain concentration (*i.e.* a certain proportion in the air breathed). A higher concentration may cause instantaneous death. The only known com-

pounds which, in concentrations practically obtainable, produce immediate death, are those containing cyanogen. The chief disadvantage of these is that when the concentration is not sufficient to cause death they have no effect at all, or only temporary faintness, headache or heart trouble. The other lethal compounds may have immediate injurious effects, such as headache, nausea, etc., and in high concentrations may cause death in a short time. In concentrations which are not strong enough to kill, they may cause casualties, which have the disadvantage that as the action is delayed a man may be able to continue fighting for some time after exposure. Thus in the case of phosgene, a man who does not notice that he has been gassed may die suddenly as much as 48 hours later.

The irritant gases are divided into (a) Lachrymatory (affecting the eyes), (b) Sternutatory (causing sneezing), (c) Vesicatory (blistering).

Lachrymators, on account of the extreme sensitiveness of the eye, can produce an effect in extraordinarily weak concentrations, such as 1 in 1,000,000 parts, or even less. Protection can be given by well-fitting goggles, but goggles cannot be used when there is a chance of exposure to lethal gases, because they would interfere with the gas-mask. The presence of lachrymators therefore entails the wearing of the complete mask, with all its disadvantages. The principal bases for lachrymators are iodine and bromine.

The sternutators were originally considered from the point of view of putting a man temporarily out of action by a violent fit of sneezing. A more important use suggested itself later, namely, that a man could be prevented by sneezing from adjusting his gas-mask, and would thus be exposed to the action of lethal shell. Similarly, if a sternutator could be found to penetrate the gas-mask it would be impossible for the wearer to keep it on. Early in the war there were many reports of the intended use by the Germans of red pepper and capsaicin. Many experiments were tried by the British with capsaicin and similar agents, but they did not give good results. In the summer of 1917 the Germans introduced shells filled with diphenyl-arsenious chloride (Blue Cross shell). They used a great many of these, especially on the French front, but not with any great success. In view of their effect on the wearing of the gas-mask, these irritants require further investigation.

Vesicants are only practicable when they act in vapour form. In that case they are by far the most effective of all the irritants, as they attack the skin and all the mucous surfaces. Those first considered were effective only when they reached the skin as liquids, a condition difficult to secure, and they were therefore dismissed. But the German "mustard gas," also known as Yellow Cross and Ypérite (Sym. dichloroethylsulphide), acting as a vapour, was immediately successful. It first appeared in July 1917. It attacked the skin through the clothing, causing burns and irritation which might last from a fortnight to two months. Acting on the eyes it caused blindness, usually temporary. Acting on the bronchial tubes it might cause bronchial pneumonia. It might affect the heart, and also the stomach, causing vomiting and diarrhoea. These effects were sufficiently serious, in view of the large numbers of casualties which were produced, although the proportion of fatal cases was small, being no more than about 3%. In this connexion it should be noted that substances of the irritant class may also be lethal in high concentrations, *i.e.* in concentrations higher than those necessary to produce the characteristic temporary disablement.

A very important consideration in the use of gas is what is known as "persistence." Cylinder gas, travelling with the wind, is effective over a particular area only while it passes; but liquid gas splashed on the ground in minute particles from a shell, or left in the ground by the smothered burst of a shell, may be effective for some time, and gases are classed as of "high persistence" or "low persistence" according to the time during which their effect remains. This depends on the rate of evaporation. A strong lachrymator may be effective on the surface for perhaps twenty hours; other irritants, such as mustard gas, may remain effective for days in suitable meteorological conditions. Left

under the surface they may remain latent for still longer periods, and take effect when disturbed by digging. It will be understood at once that this is a question of great tactical importance. For instance, a bombardment with "high-persistence" shells of trenches shortly to be attacked would be an obvious mistake, since the attacking troops after capturing the trenches would not be able to occupy them. On the other hand, in a raid on trenches which it was not proposed to retain it would be correct to burst bombs of "high-persistence" gas in trenches and dug-outs. So also in using a gas barrage or in bombarding an area, high-persistence shells should not be used if it is intended shortly to attack over that ground. The use of vesicatory shells especially will deny a given area to both sides, or "nullify" it. Gas shell is now classified not according to its physiological effect, but according to tactical use, viz. as persistent or non-persistent, the former being used for neutralization (e.g. mustard gas) and the latter for surprise destructive bombardment (e.g. phosgene).

The questions may be asked—why use the irritant type of gases at all if lethals are available? and among the lethal gases, why not use only the most powerful, namely, those which produce immediate death? In both cases the answer is found in the question of quantity. The specific lethal gases will only produce their effect in very high concentrations, which means that a large number of shells must be used simultaneously over a certain area. Shells of other types, though they may not kill at once, will produce casualties in very much lower concentrations. The question of the number of shells to be fired to produce a given effect is of great importance, not merely from the point of view of expense and the call on manufacturing resources, but still more in the field, as regards the number of guns required to fire the shells, the exertion of the guns' crews, and the question of transport. Again, an effective lachrymator will produce an atmosphere that cannot be endured in one-thousandth part of the concentration which the lethal shell would require for its purpose. This is a matter of great importance, especially in neutralizing enemy batteries. Lachrymators rather went out of fashion towards the end of the war, not only because the great munition efforts of both sides had produced an enormous quantity of lethal shell, but still more because the neutralizing effects and harassing effects which were their *raison d'être* could be obtained better by mustard gas.

Vesicating shells, which are of high persistence and whose effect is often delayed, are specially useful against targets behind the front line. Although a trench or strong point which it is intended physically to occupy cannot be subjected to mustard-gas bombardments, the use of this substance in combination with an attack round the flanks proved very valuable in reducing defences which could not have been carried either by assault or by explosive bombardments. The possibilities also of mustard-gas barrages in defence are very great. They should be used against communications, depots, railway stations, and especially staff offices, telephone exchanges and everything that affects the enemy's organization. An entirely odourless vesicator and one which does not produce a smoke easily recognizable will be particularly effective in this way.

As a general rule both lethal and irritant shells should be used in scientific alternation. With lethals, of course, the object is to catch the enemy unprotected by his masks, and in order to get a good effect a large number of shells must be fired at once. Such effects may be specially aimed at when large numbers of troops are known to be concentrated in certain places, previous to an assault. But it is also an important object to force the enemy to wear masks as long as possible, not only to fatigue him, but to exhaust the protective powers of the mask. This can be effected with irritants, and after some hours of bombardment with these, fresh bursts of lethal shells may be tried.

Methods of Employment.—The study of the characteristics of gas-clouds is very complicated. The cloud may consist of true gas, or minute drops of liquid, or infinitesimally divided solid particles. The last are known as "particulate clouds," and in their behaviour resemble a colloid vapour. Their action has to be studied physically and electrically as well as chemically.

The production of cylinder clouds, of course, is simple. The critical temperature of the gas employed must be above normal temperature. The liquefied gas is filled into a cylinder with a nozzle on the principle of a soda-water syphon. The cylinder is placed in position in the trench, and the nozzle is provided with a short length of pipe, which is placed on the ground in front of the trench, and ensures that the gas on issuing is well clear of it. The valve being opened, the liquefied gas is discharged with some force, and as its evaporation causes a fall of temperature a heavy cloud is formed which travels with the wind. The necessary density of cloud is obtained by opening simultaneously a sufficient number of cylinders per unit of length of trench, other cylinders being held in reserve to continue the discharge for the time considered necessary. At first the cylinders were placed in groups against the front wall of the trench. This method had the disadvantage that a cylinder might be burst at an inopportune time by an enemy shell, and later the Germans placed their cylinders under the floor of the trench, protected by sandbags, etc., while the British placed theirs in chambers excavated at some depth below the parapet.

The earliest cloud discharges lasted only twenty or thirty minutes, or at most an hour, the necessary concentration being calculated at ten tons of the chemical per km. of front attacked per hour. By the end of 1916 the French were using 100 tons per km. per hour, and the emission was continued for three or four hours. In the course of 1918 the British Special Brigade was using 200 to 250 tons of gas per km. per hour, and keeping up the cloud for eight, ten or even fourteen hours. The transport of gas cylinders up to the front trenches was naturally extremely laborious. It was very difficult to avoid attracting the enemy's attention to the carrying and emplacement of them, and there was always the risk of cylinders being burst by the enemy's shell. The results that were achieved under such conditions testify in the highest degree to the devotion and courage of the troops employed. The enormous discharges of 1918 were effected by loading the cylinders on trolleys and running them up to the front trenches on light railways just before they were to be used. The nozzles were opened by an electric device.

On the other hand the use of gas in shells presented all sorts of difficulties from the outset. It was first necessary to find gases that could withstand the shock of discharge from the gun and the effect of bursting the shell. Some of the most lethal gases could not be utilized because they were chemically unstable, and were liable to become decomposed into their constituent elements by shock. The cyanide compounds were to some extent of this nature, so that the Germans never used them. The French discovered a stable cyanide compound in which they had considerable faith, and the British used them to a certain extent.

Some stable lethal gases were found in due course, in addition to the irritants, and a whole series of problems presented themselves. The first question was the possible effect of the gas on the material of the shell. Some gases, such as phosgene, had no action on steel or cast iron. Others required containers of lead or porcelain; the French had a very effective method of blowing a glass lining into shell. The methods of scaling the shells and of filling and closing them offered merely technical difficulties, though these were considerable. The most suitable means of opening the shell was the next question, which had to be first considered, and then practically tested. The first gas shell used by the Germans contained a large proportion of high explosive; it is not known whether the idea was to follow the Hague Declaration in that the sole purpose of the shell should not be to spread deleterious gases, or to have a "double-purpose" shell, destructive and toxic. The result, however, was to produce an inferior explosive shell, while most of the gas was dissipated by the explosion.

The British efforts were directed at first to getting the maximum amount of gas into a shell and releasing it with as little disturbance as possible. The gas-cloud would issue in the form of an oblate spheroid which travelled down the wind, gradually enlarging and being diluted by the air. Without wind the gas would remain on the surface, settling down in trenches or depressions of the ground. For opening with the least amount of

disturbance cast-iron shells were indicated, as they required practically no bursting charge; but cast-iron shells have the drawback that they hold much less liquid than steel shell, because the shell wall has to be very much thicker to resist the shock of discharge. It was eventually found that not only every gas but every nature and every calibre of shell required a different bursting charge, and sometimes a different explosive. These all had to be determined experimentally. Later it appeared that certain liquids required a more powerful burster in order that they might be distributed in a fine spray. When a solid was introduced, in the shape of diphenylchlorarsine, a still more powerful burster became necessary in order that the solid might be atomized and dispersed as a cloud. Thus the German 77-mm. shell contained only 125 gr. of this solid enclosed in a glass container, the space between the container and the shell being filled with 600 gr. of explosive.

While the output of chemical shells remained very small the question of cloud formation by lethal shells was of high importance. Not enough shells being available to charge the whole atmosphere over a certain area with a fatal concentration, it was necessary to rely on the effect of each individual shell cloud, which ought to pass over a man or group of men while still at full strength. With the very large quantities of shell that were available later this question was of less importance, as it became possible to produce and maintain very high concentrations over a given area or length of trench. This was facilitated by bringing the larger natures of shell into service, and also by the use of Stokes' bombs and trench-mortar shells, but still more by the Livens projector.

Since gas shells were intended to be used without considering the direction of the wind, the possible effect of a bombardment on one's own troops had to be considered, and a further range of experiments became necessary. The kind of precautions required are indicated in an extract from German Army Orders of June 30 1918:—

The following regulations for gas bombardment are made known. Minimum distance of the objective from our first line:—

(1) Wind normal or oblique towards the enemy: for all natures of gas shell the least distance must be 300 metres; below that distance projectiles fired short may fall in our lines. When the wind is steady and the ground favourable, this distance may be reduced if only a small number of projectiles are being fired.

(2) Still weather, or wind normal or oblique towards our lines:—

(a) Heavy bombardment (several thousand projectiles), ground favourable for the return of the gas towards our lines:—

Blue Cross shells (Diphenylchlorarsine—sternutators) . . . 1,000 metres (offensive).

Blue Cross shells . . . 500 metres (defensive).

Green Cross shells (Trichloromethylchloroformate—lethal) . . . 1,000 metres.

Yellow Cross shells (Sym. dichloro-diethylsulphide—vesicatory) . . 1,000 to 2,000 metres according to the number.

(b) Light bombardments (some hundreds of projectiles), when our troops have been warned and the ground is favourable:—

Gas shells of all natures: 300 to 500 metres. These distances are given for general guidance; they may be reduced or increased according to local conditions.

The influence of the state of the atmosphere and ground conditions on the use of gas is naturally of great importance. The first consideration is the wind. Lethal shells will produce the best effect with a wind of three miles an hour or less; with a wind of over seven miles they cannot be used effectively. Lachrymators can be used in higher winds up to twelve miles, but with diminishing effect. Heavy rain destroys gas effect. Dry weather and a bright sun tend to dissipate the gas quickly. The most favourable atmospheric conditions are little or no wind, moist atmosphere, and no sun. The night usually offers the best conditions for gas. As regards the effect of ground, it will be obvious that anything which protects the gas from the effect of wind assists concentration. Hollow ground, valleys, woods, areas covered with undergrowth, and villages make therefore good targets.

Field Organisation.—The earliest British experiments on a field scale were made with extemporized appliances on the nearest open ground to the source of production of gases under trial. Some experiments not involving danger were made on a ground that had been acquired for flame-projector and explosive trials

at Wembley, and at the Clapham School of Trench Warfare, but it was soon evident that a properly organized experimental ground was essential, and after much search a site was found at Porton near Salisbury. Here trenches and dugouts were made, artillery ranges prepared, and gradually a complete installation provided of laboratories, mechanical workshops, magazines, filling-rooms, gas-chambers, etc. It was now possible to experiment on a really scientific basis, while the ground available gave space for trial of many other trench-warfare requirements, among which smoke and incendiary shells and light signals were of great importance. Porton thus became the headquarters of the practical study of gas warfare. The laboratory experiments there were confined, however, to examination of the results of trials. Other laboratory work was done at the Imperial College, at Cambridge and other universities, and in private laboratories.

The first British experiments with gas-projectors showed the difficulties that were likely to arise with defective apparatus, or from changes of wind in the trenches; and it was realized at once that, for the handling of the new weapon, it was necessary to have some chemists in the front line who should be trained in the handling of the material, and who could also advise the troops on the effects of it. The suggestion of raising a Chemical Corps was put forward and approved; and as a result all the universities were invited to nominate students of chemistry, while at the front chemists were withdrawn from the ranks for the new corps. This was the beginning of the Special Brigade R.E. in which a certain number of selected students and officers already serving were given commissions, while others were appointed as non-commissioned officers to give them the necessary authority and position.

A certain number of officers and men were also appointed to it who were not chemists but had experience at the front. Thus the officer commanding the Special Brigade suggested working the men at cylinder emplacements in the trenches in pairs; one a chemist and the other an old hand from the infantry. The importance of having trained scientific men in the brigade was shown by the number of valuable suggestions that emanated from the officers, as well as by their extraordinary keenness and effectiveness in the field. After a short time selected officers from the brigade were appointed as chemical advisers at headquarters of armies and corps, and a central laboratory at General Headquarters was started for examining enemy gas and anti-gas appliances and dealing with urgent problems.

Organisation in England.—In June 1915, upon the formation of the British Ministry of Munitions, the personnel hitherto engaged on chemical warfare was transferred to the ministry. The time had come for rapid expansion, and a Trench Warfare Department was created by the minister which was responsible for both design and supply, not only of chemical war material but grenades, trench mortars and projectiles, smoke shells, signals and the countless other requirements that modern trench warfare had made necessary. The staff, rudimentary hitherto, was increased in proportion to the requirements of experiment and manufacture, and a scientific advisory committee was formed of eminent specialists in chemistry, physics and physiology. This new department was unique in combining the functions of research, design and supply. The other departments of the ministry were concerned with supply only, in response to the demand of the War Office. It was decided after much discussion that this exception should be made for the Trench Warfare Department, because it was recognized that in dealing with so many entirely new products, the manufacture of most of which was attended by considerable danger, it was essential that the designers should be in the closest possible touch with the manufacturers, should be able to explain what was being aimed at, and should advise on difficulties as they arose. The resultant close contact enabled them also to modify their designs during manufacture when necessary; to take account of facilities for supply and manufacture; and to order supplies in advance as soon as a new production was foreseen.

There is no doubt that this was the right procedure, as was proved by the rate production up to the end of 1915. The weak

points were that the department had to communicate with the front through the War Office, which caused delays and mistakes, and that defensive arrangements, the provision of gas masks, etc., so intimately connected with offensive research, remained with the War Office. But, for the rest, the department had only to obtain the approval of the War Office for new designs and material, with an indication of quantities to be provided, and could then make its own arrangements. To this, however, one very important exception had to be made; they were not allowed to design or manufacture gas shell, and as other branches were not in a position to design them this led to serious delays. These delays were accentuated by the fact that in 1915, when shells were scarce and the value of gas shell had not been proved, the authorities responsible for shell generally were very unwilling to allocate shells to gas.

Gas warfare both in France and Russia began with divided control, and as this gave very unsatisfactory results, in each country after some time a separate organization was formed with complete control of design and supply. In the autumn of 1916 for instance, when the British were scarcely beginning to produce gas shell, Russia with her poor manufacturing resources was already sending to the front a steady supply of 25,000 gas shells a week for field guns. The British on the other hand, having begun on the right path, had left it. Within the ministry, at the end of 1915, research and supply were separated. It was assumed that they would work together as closely as before; but in fact, the Supply Department immediately and inevitably drifted away, and not only lost the advantage of supervision by the designers, but began to research on its own account, thus causing overlapping and confusion. Early in 1916 a Department of Munition Design was formed, and the Trench Warfare Research Department passed under the control of that department. Their work was then much restricted, and was directed by a department which knew nothing of it, and which intervened between them and the War Office. The confusion and friction that followed had a serious effect both on progress and output.

In the summer of 1917 the large number of casualties caused by the German mustard-gas shells occasioned some anxiety on the British front, and it was asked why the British army had not something equally effective. The reason was that since 1915 research in irritants had been discouraged; and as the Chemical Research branch was not in direct touch with G.H.Q. the question had never been properly discussed. In the result, in Oct. 1917 the Chemical Warfare branch was reorganized and considerably expanded. It had more direct communication with the front, and the Defensive organization from the War Office was amalgamated with it. The Supply Department was however kept separate.

In April 1918 the Trench Warfare Supply Department was broken up. This was the opportunity to restore the supply of gas and gas shells to the Chemical Warfare branch, especially as they already had supply on the "anti-gas" side; but the manufacture of gas went to the Department of Explosives Supply, and the filling of shells and bombs to the Department of Gas Ammunition Filling. This continued until the Armistice.

Objects of Gas in Warfare.—It must be clearly recognized that in the use of gas a new weapon of war has been found, which supplements without displacing the existing arms. Explosive and shrapnel shell have their limits. A very small amount of cover will give entire protection against shrapnel, and deep dugouts will protect against the most powerful explosive shell. When the enemy has provided cover and such shell become ineffective, gas becomes effective. A gas heavier than air will settle in trenches and remain in them; it will drop down the approaches to the deepest dugouts and permeate them. According to the nature of the gas, whether lethal or irritant, the enemy, if unprovided with gas-masks, will then be either killed or driven up into the fresh air. In the latter case, he comes once more under the action of the ordinary artillery shell. If he has masks he can remain under cover, but the masks must be worn, not only until the bombardment stops, but afterwards until the shelter is cleared of gas.

In trenches also, and in the open, as long as there is gas, masks must be worn, and the troops fight under a heavy handicap. This condition may be kept up indefinitely with a slow bombardment of irritants and occasional bursts of lethals. In the case of a smoke-cloud discharged for eight or ten hours continuously the protection afforded by the mask with its refills will be exhausted, and the troops attacked have three alternatives: to counter-attack, which without prearrangement and the necessary supports is hopeless, to die at their posts, or to retire.

The effect of gas differs fundamentally from that of ordinary shell in its persistence. A bombardment with explosive shell is effective only while it lasts. The moment it is over troops can move freely over the area of bombardment. With gas, on the other hand, troops cannot cross the area without masks until the gas has been dissipated.

Again, a shrapnel bullet or splinter of explosive shell may hit or may miss; troops may pass through such a barrage with considerable losses, but still in sufficient numbers to attack. The gas cannot miss. If enough has been discharged over a certain area to give the necessary concentration, every man passing over that area without a mask will be affected.

In clearing up a captured line of trenches during an advance, gas bombs are most effective for bringing the enemy out of deep dugouts. For this purpose a non-lethal irritant of low persistence, which will penetrate the enemy's mask, may be used.

There is also the question of the effect of gas behind the lines. Such a discharge of cloud-gas as has been described may travel for miles before it is sufficiently diluted to lose its destructive effect. A long-range bombardment of an artillery or engineer depot will make it impossible for some days to handle the material without good protection.

That gas shell had a real military value as compared with ordinary shell is proved by the fact that both combatants used them so freely in the last year of the World War. Thirty per cent of the total American casualties were caused by gas, and no estimate can even be attempted of the general loss of efficiency brought about by the necessity for wearing respirators. Sillevaerts gives the following German order for the proportion of different shells to be used in the bombardment before the attack on the Aisne on May 27 1918:—

Object	Explosive	Blue Cross	Green Cross
1. Counter-battery and long-range bombardment	20 %	70 %	10 %
2. Bombardment of infantry positions			
(a) Moving barrage	60 %	30 %	10 %
(b) Back barrage	30 %	60 %	10 %

Experience showed also that batteries attacked by gas shell were generally put out of action for several days.

Future of Gas Warfare.—Such then is the new weapon. Its potency is undeniable, as is the fact that it is effective where other weapons fail. The question is, will its use be continued? The answer, from a military point of view, may be found in the fact that, if one belligerent uses gas and the other does not, the former will in all probability win. Since experience has shown that conventions made in peace-time are not always respected when war comes, the argument that no nation can allow its existence to depend on the security of a convention prohibiting the use of such a weapon, is even strengthened by the fact that, after the lessons of the World War, nobody in 1921 could predict what further chemical or physical developments scientific investigation might produce in the future. Great advances might well be made in the discovery of gases that would penetrate any mask hitherto designed, and in the utilization of them. The nation that cares for its safety must therefore keep pace with such discoveries and with the means of protection against them. To prevent the production and the study of toxic gases is impracticable, because many of them are either necessary elements or by-products of manufactures essential to modern industries in peace-time.

As for the ethical side of the question, it must be considered dispassionately. Every new means of warfare, intensifying its

effectiveness, has caused an outcry when first introduced. Gas warfare, *per se*, is not necessarily or exceptionally cruel. For instance, if it were conducted on both sides with cyanides, successfully adapted to war purposes, the resultant deaths would be the most merciful that history has ever known. It is to be noted that in the World War less than 3% of the total gas casualties were deaths, whereas some 20% of casualties due to other weapons resulted in death either on the field or in hospital. The use of gases may be guarded by future conventions so as to prevent unnecessary suffering, just as explosive bullets were barred. Thus chlorine might be forbidden, because there is no death more painful than that by suffocation. But the utmost that seems possible is to limit by convention the use of poison gases in such a way that a breach of the convention will not place the offending combatant in a definite position of superiority.

It is infinitely to be deplored that gas warfare was ever introduced. It certainly adds a new horror to war. It imposes fresh burdens on the soldiers, who may ultimately be forced to spend most of their time in gas masks, even when far behind the lines. The most terrible thing perhaps about it is that, since it is impossible to remove all non-combatants from a zone of war, and equally impossible to provide them with masks, thousands of them must inevitably perish. For this reason alone it would be well if gases were forbidden. To forbid them, however, is one thing; to prevent their use is another. And unless more effectual means than were within sight in 1912 can be devised to make this (or any other) form of warfare impossible, considerations of national security must inevitably prevail.

Gases used in the World War.—The following are some of the more important gases used during the World War:—

Cyanogen Compounds.—Effect, in concentrations of as much as 1 in 1,000, immediate death. In weak concentrations, giddiness, headache and pains about the heart, but ultimately complete recovery. Used by the French and the British in shells as a mixture of 50% hydrogen cyanide, with arsenic trichloride, stannic chloride and chloroform.

Chlorine.—Attacks the respiratory tracts, forming in contact with moisture hydrochloric acid which destroys the tissues. Has a reflex action on the system generally, causing vomiting and diarrhoea. In high concentration may cause immediate death by spasm of the glottis. Only used as cloud-gas from cylinders.

Phosgene (Carbonyl chloride).—A very dangerous gas because the effect is delayed, and the victim is often not aware that he has been gassed. May cause sudden death as much as 48 hours after exposure. Very much used both in shells, and with chlorine as cloud-gas.

Diphosgene (Trichloromethyl chloroformate).—Effect similar to that of phosgene. Much used in shells, both alone and with other gases.

Chloropicrin.—Acts on the respiratory system like chlorine but more strongly. Is also a lachrymator. Much used in shells generally in combination with other gases.

Bromine.—Action similar to that of chlorine. It can be used conveniently for gas-clouds on account of its high boiling-point, but it forms the basis of a large number of powerful lachrymators. It was much used by the Germans as a lachrymatory shell-filling in the form of benzyl or xylol bromide and brominated ketones.

Ethyl iodacetate.—British lachrymator. Very marked action on the eyes, ceasing the moment the neighbourhood of the gas is left. High persistence.

Bromacetone, Chloracetone and Bromomethylchloracetone.—Much used in shell. Powerful lachrymators, and asphyxiating or lethal in high concentrations. Moderate persistence.

Diphenylchloroarsine.—Solid, dispersed in clouds of fine particles. Cannot be kept out by ordinary masks. Powerful sternutator, producing also coughing and sickness; in strong concentration, causing insupportable headache. Much used in Blue Cross shells by the Germans.

Diphenylcyanoarsine.—Similar to diphenylchloroarsine, but with a more powerful action. It superseded the latter as a German Blue Cross filling.

Mustard Gas, Yperite, or Yellow Cross.—(Sym. dichlorodiethylsulphide). Vesicant. Attacks the skin even through the clothing with a blistering or burning effect. Affects all the mucous surfaces. Acting on the eyes causes blindness, usually temporary. Acting on the respiratory tracts may cause death by bronchial pneumonia. In favourable weather remains effective for several days.

Livens Projectors.—The use of lethal-gas shells, which require a very high concentration, implies the necessity of bursting a large number of shells simultaneously along a given length of trench or over a given area. With artillery shell this necessitates a concentration of every available gun within range on the point of attack,

and needs a certain amount of preliminary arrangements. With Stokes or trench-mortar bombs whose contents are much larger, and especially with a Stokes gun which can be fired very rapidly, a smaller number of pieces can be used. But probably the most effective means of obtaining a high concentration was the projector devised by Captain Livens, R.E. This consisted originally in using an old gas cylinder, with its top cut off, as a mortar; a hole is dug in the ground and the projector placed in it, resting on the ground at an inclination of 45 degrees and pointing in the required direction; the breech of the cylinder is backed up with a strong base-plate about 12 in. square. The propelling charge is contained in a tin box placed at the bottom of the projector and divided into compartments; the propellant explosive is placed in the compartments in bags, the number of bags being varied according to the range required. The projectile is a steel drum with rounded ends, 21 in. in length and just fitting into the cylinder, which has a bore of 8 in.; within the drum is a central tube running down its length, about 1 in. in diameter, which contains the bursting charge. The projector is fired by an electric fuse, about 20 of them being connected up with an exploder. These 20 may all be placed side by side in the same trench, and will constitute a battery. By these means as many as 4,000 of these projectors have been placed in position behind the front trenches in a night and fired simultaneously. Naturally, neither range nor direction are very accurate, but they are sufficiently so to give a very high concentration of gas over a small area, in some cases sufficient to kill men even when wearing their respirators. These projectors proved so useful that they were employed also for incendiary and high-explosive charges, and were immediately copied by the Germans, who feared them more than any of the other chemical warfare methods of offence employed by the Allies.

Incendiary Materials.—The beginning of the war showed nothing particularly new or useful in the incendiary materials used by either side. Quite early in the war a German incendiary shell was found to contain white phosphorus and a very inflammable celluloid mixture. In England petrol bombs were tried and containers filled with rags soaked in petrol. The results were not important. Phosphorus by itself was not a reliable incendiary agent, though a shower of molten phosphorus descending from a shell burst in the air had a good moral effect.

The first demand for incendiary materials for the British army arose from the necessity of burning the long grass in No Man's Land during the summer of 1915, to prevent the enemy from using it for cover. To meet this demand a small catapult grenade filled with phosphorus and petrol was supplied, it being found that a small addition of phosphorus gave a more certain ignition of the petrol. Phosphorus, however, was far more useful as a smoke-producer than as an incendiary. A very important advance was made when a method of utilizing thermit in shell was discovered. Thermit is a mixture of iron oxide and aluminium which when ignited by a suitable primer burns with an intense heat, which has been estimated at 5400° Fahrenheit. It is used commercially for welding, and has been used in the army for such purposes as destroying guns, a small quantity of it being placed in the bore and ignited; the result of this is to make the gun useless, as when the thermit cools it is found to be firmly welded to the surface of the bore.

The ordinary ignition, however, is too slow for the purpose of an incendiary shell. Experiments were made with special ignition powders in Stokes shells but without good result. In Jan. 1916, however, thermit was tried with a bursting charge of ophorite which gave excellent results, the thermit being instantly raised by the discharge to melting-point so that when the shell was burst in the air it let fall a shower of molten metal. Ophorite was an explosive that had recently been discovered by Professor Thorpe, which while less powerful than the ordinary high explosives, had the advantage that it could be fired by a fuse without a detonator.

Thermit employed in low-velocity projectiles such as Stokes gun shells became a very valuable incendiary agent; with artillery shells it was not so useful, as satisfactory ignition was difficult to obtain.

Experiments were also tried with fine coal-dust distributed in the air but the results were not practical.

Anti-gas Defences.—About the end of March 1915, in consequence of the increasing rumours that the Germans intended to use poison gases, the British War Office asked Sir William Ramsay's committee to consider what gases might possibly be used, and what would be the best means of protection. Before the committee reported, the cloud attack of April 22 was made. The circumstances were explained to Sir William Ramsay by telephone, with the remark that the gas was probably chlorine, and the next morning he came to the War Office with several sample mouth-pads made of flannel or wool soaked in hyposulphite of soda. An appeal was made through the Press to British women to furnish 1,000,000 of them at once, and thanks to their response and the efforts of the Red Cross the necessary quantity came in two or three days, so that within a fortnight every man

in the British army at the front was supplied with this form of respirator. Although rudimentary, it gave useful protection.

Meanwhile chemists and physicists were at work on both the French and British fronts investigating the facts and advising on temporary protection. The day after the first gas attack, instructions were issued to keep buckets of solution of bicarbonate of soda in the trenches; the men were to dip their handkerchiefs in the solution and tie them round their mouths in case of gas attack. More efficient respirators were considered, also the use of large fans for clearing the trenches of gas, and direct fighting of the cloud by spraying neutralizing agents into it. Thousands of Vermorel sprayers were sent out, for clearing trenches and dug-outs. The dispersal of clouds by shelling and by explosions was tried, also lighting fires in front of the trenches to heat the cloud and cause it to rise. None of these methods were really effective in stopping clouds, and attention was gradually concentrated on direct defence by masks.

The first improvement on the respirator, which was introduced in the War Office a few days after the attack, was known as the Smoke helmet or Hypo helmet, a kind of Balaklava helmet made of flannel or thin serge, covering the head loosely and reaching below the neck, round which it was tied. The eye-pieces were made of mica. This helmet was impregnated with hyposulphite, soda and glycerine solution, and carried in a waterproof bag. It gave satisfactory results for some time. Pending the complete supply, the increasing use of lachrymating shells by the Germans gave rise in June to a demand for goggles.

During 1915 the helmet was improved by the introduction first of phenates to protect against phosgene (when it is called the 'P' helmet) and later by the further addition of Hyomine (when it was called the P.H. helmet), to ensure protection against phosgene and prussic acid. A respiratory valve and mouth-tube was also inserted in the P. and P.H. helmets, and this added to their comfort and efficiency.

As the use of other gases was foreseen, such as phosgene and hydrocyanic acid, a more effective protection than could be put into cloth became necessary. Thus the "box respirator" type was developed, and gradually issued during 1916. The general type of these consisted of a mask or face-piece into which entered a flexible tube issuing from a metal container which held chemicals, through which the air was breathed. In the earlier patterns the air passed through the tube into the space between the mask and the face; but as it is very difficult to get the mask to make an airtight fit round the face, the tube was extended and ended in a mouth-piece which fitted closely to the lips, while the nostrils were closed by a nose-clip. The container and mask were carried in a knapsack. The mica eye-pieces were replaced by celluloid, and eventually by triplex glass, which does not splinter when broken and remains airtight.

The introduction of a container for the neutralizing and absorbing agents gave free scope to chemists to provide against all kinds of poison gas. In this connexion it is worth recording that the British gas-mask did in fact give efficient protection from its introduction to the end of the war.

The containers were filled with alternate layers of charcoal and composition granules. The charcoal absorbed gases, and the granules, whose composition could be varied indefinitely, absorbed and neutralized them. The container had the further advantage that its contents could easily be renewed.

This type of respirator continued in use until the end of the war but was subject to continual improvement. No effort in this direction could be spared seeing that any defect in the manufacture or adjustment of the mask might mean death to the wearer. Constant progress was made with the British and French patterns, and the Americans when they entered the war took up the question very thoroughly. They, like the French, had the advantage that their chemical service was a separate branch of the army with the offensive and defensive sections working under the same head. Among other defects the air-tight fitting of the mask to the face needed a great deal of study and experiment. The eye-pieces gave trouble because moisture would condense on them both outside and in. This was partly cured by

using a soapy solution on the glass. The whole apparatus had to be made as little cumbrous as possible, and so adjusted with its knapsack that it could be very quickly taken out and put on. The use of the mouth-piece and nose-clip was very trying when worn for long periods.

In 1918, the Tisset mask was introduced in France, which did away with the mouth-piece and met the difficulty of condensation by causing the cold air from the inlet-tube to pass across the eye-piece in entering the mask. This type, which was adopted and improved by the Americans, was known as a "single-protection" respirator. Its weak point is that if the face-piece is torn, or does not fit properly, protection is lost.

The provision of the charcoal for the containers opened up a wide field of investigation. For absorbent purposes a very dense charcoal was required. Experiments made in the United States showed that coconut-shells gave the best form of charcoal for the purpose, but their preparations were on such an extensive scale that they calculated that they would require a supply of 400,000 tons per day of coconut-shell, which were obviously not obtainable. After coconut-shells the best carbon was obtained from fruit-stones such as peach, cherry, etc., and Brazil and other nut-shells. Carbon obtained from hard wood, such as the ironwood was of less efficiency.

The scale on which the United States worked is shown by the following figures given by Farrow of the production of protective materials up to the date of the Armistice, the great bulk of which were produced in the last four months of the war:—

Material.	Production up to Nov. 11 1918.
Respirators	5,276,515
Extra canisters	3,144,485
Horse masks	366,529
Bleaching powder (tons)	3,677
Extra antidimming (tubes)	2,855,776
Sag paste (tons)	1,136
Dugout blanket oil (gallons)	95,000
Protective suits	500
Protective gloves	1,773
Dugout blankets	159,127
Warning devices	33,202
Trench fans	29,977

The sag paste mentioned in this list was an ointment used for the skin to protect it against mustard gas, the protective suits and gloves being for the same purpose. The blankets, which were to seal the doors of dugouts, were made of specially woven cotton treated with a specially heavy oil. The warning devices were mainly watchmen's rattles and Klaxon horns.

From the beginning gas schools were established on all army fronts, where men were taught the use of the masks and made to enter gas chambers with masks on to get proof of the protection afforded. Similar schools were established by all the nations at their gas defence headquarters, where experiments could be tried. The result of such work is well shown by the following extract from Farrow's description of the American gas service:—

"There was a special field-testing section of the Gas Defence Division composed of about 150 men who were trained to the minute in field manoeuvres and did most of their work in gas-masks. They were constantly in and out of gas with regular production and experimental masks. They played baseball in them, they dug trenches, laid out wire, cut wires, and fought sham battles at night, both with and without actual gas. The work of this section even went so far in the case of the later design as to include a test where six men worked, played and slept in the masks for an entire week, only taking them off for 30 minutes at each meal-time, and each day entering high concentrations of the most deadly gases without any ill effects whatsoever to the wearers. When it is remembered that eight hours was the limit of time which a strong man could wear the old-type mask, something of the efficiency of the new mask may be realized."

These of course are experimental results with selected men, which generally differ widely from those obtainable in the field. They only show the great improvement made in patterns of respirators before the end of the war. The fact remains that any efficient respirator is a source of fatigue as well as a great inconvenience. British experiments have shown that in hill-climbing with and without respirators, there is a marked difference in the increase of heart rates and rates of breathing under the former

condition. Up to 1921 what had been done gave good protection with reduced inconvenience. But much yet remained to do; indeed, complete protection both at the front and in the rear areas might well be unattainable. (L. J.)

POLAND (see 21.902*)—The partition of Poland was the one great crime of the 18th century for which no redress was afforded by the settlement of Europe after the Napoleonic wars, and it eventually proved one of the causes of the World War in 1914, though the Poles had become apparently more or less reconciled by that date to working out their destiny under Russia, Prussia and Austria. In the earlier article their history has been sketched up to 1863, but it is necessary here to make some brief reference to former times as well as to give the outlines of its development from then up to 1914.

RUSSIAN POLAND.—"The insurrection of 1863," says Stanislaus Kosmian, "helped the greatest enemy of Poland and the Polish cause to success. On the ruins of the Polish revolution rose . . . the system of Russification in the Empire of the Tsar." Under the new name of the Governments of the Vistula the Polish provinces formerly known as "Congress Poland" or the "Kingdom of Poland" were placed in the hands of military governors whose duty it was to suppress every tendency towards Nationalism and to ensure complete subservience to Russia. Russian became the official language of the country and it was enforced in all public business. In 1869 it was adopted as the official language of higher and secondary education and in 1885 the use of the Russian language became compulsory in the primary schools. The publication of articles in Polish was forbidden and the teaching of the language was punished by fine and imprisonment. In 1876 Russification was extended to the courts of justice and Polish officials were replaced by Russians. It cannot however be said that the policy was consistently enforced; it was for instance mitigated under Count Berg who succeeded Milyutin in 1867 and devoted himself to conciliating Polish society, and again by Count Schuvalof and Prince Imeritinsky, successors to the Draconian Gen. Gurko who reigned from 1883 to 1894. Roman Catholicism was, however, from the first recognized as "the backbone of Polish Nationalism" and consistently attacked. At the outset the monasteries were closed, the ecclesiastical lands confiscated and the Union with Rome assailed by compelling Uniates to become Catholics. This religious persecution was carried on with very slight intermittence until 1905, when religious freedom was first permitted.

The most interesting feature in the process of Russification, however, was the attempt made to break the power of the old historic families and bring the peasants into close union with Russia. The emancipation of the peasants which had been urged before the revolution was effected by the Ukases of 1864. Each peasant, whatever his tenure had been, and the mass of the landless became freeholders, which was a constant cause of class friction, and they were allowed to retain their right of free access to the forests and pastures of the landlord. To the landlords compensation was given in the form of Treasury Bonds so that they might have a lasting interest in the maintenance and solvency of the Russian Empire. Village affairs were placed in the hands of a Commune (*Gromada*) consisting entirely of peasants, who from ignorance and inexperience soon fell under the influence and mastery of the officials; while the landlords were represented in the organization of the district.

The basic idea of the system was the accentuation of class divisions, for it was hoped thus to create a class independent of, and antagonistic to, the Polish landlord and bound by ties of gratitude to Russia. These hopes were not realized for it was these peasant communes which provided centres for the educational movement at the end of the century and foci for the spread of the idea of Polish nationality.

From the emancipation of the serfs can further be traced the economic changes which took place in the latter half of the 19th century. By the splitting-up into small parcels of the large estates an ever increasing class of peasant proprietors was instituted because the small freeholders, who included in their numbers members of the smaller gentry or *Schloszka*, as well as

the former serfs, desired to increase their holdings and found themselves more and more able to pay the prices demanded by the landlords. Though the kingdom of Poland was and remains essentially an agricultural country, a great industrial change has also taken place. Whereas in 1863 the towns were still in a primitive state of development, by the end of the century great industrial centres had appeared. Competition with Russian industry was a different thing to competition with German industry, especially under the protection of the Russian tariff wall. Hence the growth of a strong middle class in which the Jews took a considerable part, some of the leading Jewish families even marrying into and being received as part of Polish society in Warsaw. The economic development became a strong bond of union with Russia and Polish textiles penetrated through the empire as far as Turkestan.

The practical exclusion of the Poles from the Russian army and administration threw back the abler and more ambitious of the upper classes among them on other employment, and strengthened this middle class and brought a new influence to bear on national life in Congress Poland. Hence practical economic reform improvement became the order of the day and the habit of theorizing on the subject of political independence fell into the background. But these improvements again could not long avoid a political aspect and hence the formation of Socialist and Democratic associations.

These Socialist societies, however, had always a Nationalist tendency because capital was largely in German and Jewish hands. The most noteworthy was the National Democratic party which came into existence before the end of the century, after several earlier revolutionary societies had failed, and set to work by means of private educational efforts to oppose Russification and definitely awaken the spirit of nationality. During the troubles which succeeded the Russo-Japanese War this party, under the leadership of M. Dmowski, formed "the army of the national movement" and in the First Duma held an important and in the Second a controlling position, but its influence was diminished by the reduction of the membership at the election of the Third Parliament. Outside Russia an important movement took place in 1908, thanks to the rise of the Neo Slav party, which aimed at effecting a reconciliation between Russia and Poland, and this platform was adopted at Pan Slav Congress held at Prague in 1908, for it was felt that the Poles would be the first victims of a victorious advance of Germany, now the most dangerous enemy (it was held) of the Polish cause.

The Russian Government was, however, recovering from the blows of the revolution of 1905 and unwilling to consider the grant of autonomy for Poland, and in the Duma even the support of the Constitutional Democrats was withdrawn when the Polish Club in the Austrian Reichsrat encouraged in 1908 the incorporation of Bosnia and Herzegovina with the Habsburg dominions. The failure of its plans caused the break-up of the National Democratic party. Its place was taken by Socialist societies antagonistic to Russia. Hence at the outbreak of the World War feeling in Russian Poland was divided.

PRUSSIAN POLAND.—The Congress of Vienna in 1815 had stipulated that the Poles should receive "a representation and national institutions." In the duchy of Posen the national rights of the Poles were recognized and for some years the policy adopted by Prussia was one of conciliation rather than oppression, while the needs of the country, such as those as to education and communications and the emancipation of serfs, were efficiently provided for. It was not till 1830 that any system of Germanization was introduced and even that was enforced with no great severity for the twenty years after 1851. But when Bismarck was able to turn his attention from Austria and France to Poland he found that under the mild rule that had prevailed the Poles had been able to develop a national movement which had indeed a parliamentary group in Berlin and had to be reckoned with in the Reichstag, but the strength of which lay in societies such as that founded by Marcinkowski in 1842 which had brought an educated class of Polish doctors, lawyers, merchants and tradespeople into existence. By means of propaganda this movement

* These figures indicate the volume and page number of the previous article.

had increased rapidly to a position more formidable than that previously engineered by the historic families and was in fact "undermining the foundations of the Prussian State." As a counter-stroke to an organization which he realized was strengthened and to some extent led by the priests, Bismarck in 1872 undertook the *Kulturkampf*, hoping thereby to crush out the growing conception of Polish nationality. The Archbishop of Gnesen-Posen, the chief leader of the Roman Catholic party, was imprisoned, the liberty of the pulpit was denied, the use of the Polish language was prohibited in the schools and attempts were made to forbid its use at public meetings. The *Kulturkampf* was continued till 1885 and in spite of its failures Bismarck's policy seemed assured of success when Dindorf was appointed Archbishop of Gnesen and the onslaught of the schools began.

The history of Prussian Poland in later years turns to a great extent upon the economic question. The industrial development of Germany had brought about a great immigration of Polish labourers to work as agriculturists in eastern Germany and as miners in Westphalia. Bismarck desisted here and after unsuccessfully trying to prevent it by expelling the immigrants essayed to counteract it by further Germanization of Poland. The appointment of the Land Commission in 1886 with £5,000,000 to buy land from Poles in Posen and W. Prussia and sell it to German colonists was the first step in the policy of German colonization which was pursued till the outbreak of the war. It is true that under Caprivi the severity of the anti-Polish policy was relaxed, but under Prince Hohenlohe it was reinforced and in 1894 the *Ostmarken Verein* was founded to obtain the trade of the eastern provinces exclusively for Germans and undermine the Polish element. Under Count Bülow the culminating point was reached in 1908 when the compulsory expropriation bill was passed with the bill prohibiting the use of Polish at ordinary public meetings. More colonists were now introduced and the sale of their land to Poles was forbidden. There were signs all through of the failure of this policy, such as the strike of the school children in 1906 against the use of the German language in religious instruction, and these signs were multiplied in the economic sphere. For here the Poles, acting on the principle that they would be masters when they were "better, more educated and richer than the Germans," had definitely set themselves to the task of defeating the Germans economically. The land that was bought for colonists was poor land and bought at high prices. The German colonists were boycotted to such an extent that they were forced to withdraw or become Polonized and the Polish position actually seemed to grow stronger as the legislation became more severe. The incorruptible Prussian official, the inexorable Prussian schoolmaster and the brutal Prussian drill sergeant had disciplined a talented people hitherto uncultured and rendered them capable of organizing and acting for themselves. By means of their coöperative societies which dealt with agriculture, finance, industry and commerce they obtained complete control of the resources of the country to the exclusion of the Germans and the Jews. They also founded unions of landowners, social, athletic and political associations. The heads of all these societies before the war formed a sort of secret Cabinet which exercised the chief power in Prussian Poland with a preponderating influence in the local Press, with power to control the supply of immigrant labour and secretly direct the boycott both of Germans and of Jews. In fact when victory came the assumption of political supremacy was not the first but the last step to complete independence.

The success of the Poles of Prussia may have been one of the elements which led Pilsudski to put his money on the wrong horse at the beginning of the World War, believing that Germany would be obliged to make of Poland a buffer State against the eternal menace of the Russian Empire.

AUSTRIAN POLAND.—The lot of the Poles in the Austrian Empire with its purely non-national basis was preferable to that under Prussia or Russia. In the former they had by fighting obtained a tolerable position. In the latter the severities were intermittent and could be mitigated by bribery. In Austria there was always a certain amount of *bonhomie* or *Gemüthlichkeit* which made official

harshness tolerable. The history, however, of Austrian Poland from 1863 to 1914 can be understood only by reference to certain governing facts, namely the imperialist opportunism of the monarchy and the racial problem presented by the rise of the Ruthenian movement in Galicia.

During the years immediately following the revolution of 1863, the Galician Poles, under the influence of bitter disillusionment, resolved to concentrate all their efforts not on recovering political unity with the boundaries of 1772, but on preserving and strengthening national unity within the Austrian Monarchy. German culture and the German language constituted the unifying and predominant force in the Habsburg Monarchy, but after the war of 1866 and under the constitution of 1867 Austrian Germans had to look for allies amongst the other nationalities. The Poles had to decide whether they would support the aims of the Federalist party with its disruptive tendencies or whether they would favour the German element and adhere to the Vienna Government. They followed the latter course and promised loyalty in return for practical concessions. Having 57 votes in the Reichsrath they were able to secure useful privileges for Galicia. In 1867 they obtained a special minister for Galicia in the Austrian Cabinet; a separate board for Galician education; the use of the Polish language in secondary schools; the use of Ruthenian being restricted to elementary schools; the use of Polish instead of German in administration and the law courts. In the following year Polish became the official language for the university of Cracow, whilst a year later it was enacted that Poles alone should be teachers in the universities of Cracow and Lemberg. From 1877 onwards the "Polish Club" in the Reichsrath became a governmental party and used all its influence to build up piecemeal the fabric of Polish autonomy in Galicia. On the whole the Poles did not use their power well. By the establishment of an academy of science at Cracow they did indeed encourage learning, but they did nothing to improve the economic condition of the people. The peasants remained ignorant and the towns were neglected. No Polish middle class was created and hence the Jewish element predominated in trade and commerce. Galicia was rapidly Polonized but only at the expense of the Germans and the Ruthenians, and on their oppression of these last the history of Austrian Poland up to and after the war to a great extent depends.

The Ruthenians have been described by Prof. Alison Phillips as a compact body of 30,000,000 occupying the country "from the north-eastern district of Hungary across the Carpathians and E. Galicia" and eastwards as far as the Dnieper. They were then ruled partly by Russia and partly by Austria, but have always been claimed by the Russians as part of their race. Indeed little doubt was expressed on the subject till a movement was started about the middle of the 19th century by certain Ruthenian scholars, who set out to prove they had a right to a separate national existence. The real impetus of the movement was economic and arose from the discontent of the peasant with the oppression of their Russian and Polish landlords. It was some 20 years before the importance of the danger of the movement was realized. From the Polish point of view it was dangerous because it challenged their supremacy in "the annexed provinces" in Podolia, Volhynia and Eastern Galicia. From the Russian point of view it was disastrous because it threatened to break up the Russian Empire. In Galicia, where in addition to the language the Greek Uniat Church formed a strong bond of union, the movement prospered in spite of the Polish efforts to suppress it, which were at first supported by the Austrian Government. This support continued as long as Austria desired good relations with Russia, that is until in 1884 it was desired to weaken the Russian colossus. Then concessions were made to the Ukrainians and the result was that in 1891 Ukrainophil deputies appeared in the Reichsrath with the development of an Ukrainian State within the monarchy inscribed on their banner. This policy had the effect of promoting a reconciliation between Russia and the Galician Poles, who thought it better that the Galician Ruthenes should be absorbed by Russia than that a Ruthene State should be set up at the expense of both Russians and Poles. To retain their ascen-

dancy, therefore, the Poles proceeded to encourage the Russophil Ruthenians, with the result that the latter were successful in 1907 in the election which followed the establishment of universal suffrage in the Austrian half of the Dual Monarchy.

In 1908 the Neo Slav Congress definitely declared that Russian Neo Slavs and Poles should act in conjunction to suppress the movement, a decision which met with no approval from the Austrian Government because Russia and later Austria were then at daggers-drawn in the Balkans and a new viceroy was appointed in Galicia who was definitely anti-Russian. The culminating point was reached in 1914, when it was discovered that the Ukrainian party was and had been for ten years past in close touch with the Prussian *Ostmark Verein* which was opposed to everything Polish. The Galician Poles had realized the complete subservience of Austria to the German Emperor and this produced a great change in their attitude to the Habsburgs, so much so, that the murder of the Archduke was received with almost indecent expressions of satisfaction, because to him was ascribed the success of the Ukraine movement in 1913.

POLAND DURING THE WORLD WAR.—Thus the declaration of war in 1914 found the Poles with no definite national policy. The various political parties were united in that they had one common end in view, the restoration of an independent Poland, but their opinions were divided as to the means of attaining this end. In Galicia the majority of the Poles were pro-Austrian. In Russian Poland the National Democrats, under the leadership of M. Dmowski, were strongly in favour of working for an autonomous Poland under the Russian crown, and this policy seems to have been supported by the majority of the Russian Poles. In opposition to this party was a strong anti-Russian element, of which the most notable supporter was Pilsudski. Having been forced to flee from Russian Poland in 1907 Pilsudski had taken refuge in Galicia, where he had utilized the *sokols* (athletic clubs) and shooting clubs for the purpose of organizing an efficient military force to use against Russia in case of war. At the outbreak of war he mobilized his forces, as the Polish Legion, and, advancing across the border, seized Kielce. The actual military result was of no great importance, but "it soon became clear that his bold decisive action had powerfully impressed the national mind."

On Aug. 14, in answer to the anti-Russian campaign which the Germans had been organizing in Warsaw, the Grand Duke Nicholas issued a proclamation announcing Russia's intention of establishing a united Poland "under the sceptre of the Russian emperor," a Poland which was to be "free in faith, language and in self-government." By the National Democrats this proclamation was welcomed as being the first stage towards the fulfilment of their aims. By the followers of Pilsudski, however, the proclamation was received with no favour: proposals for conciliation with Russia tended only to emphasize Polish divisions.

Polish resistance to the Russians took a political as well as a military form. On Aug. 16 two existing Polish organizations, the Confederation of Independent parties and the Polish Military chest (*skarb*), were merged in the Supreme National Council of Galicia, which contained representatives of all parties in the Galician Diet and Reichsrat. Though the National Council was formed with the object of offering political resistance to the Russians, it was not altogether in agreement with Pilsudski and his legionaries. It was inclined to be monarchical whilst Pilsudski was Socialist Republican. Accordingly the Council laid down the following regulations: The Polish legions were to form a separate Polish command but to be subject to the Austrian Army Command. The Polish language was to be used. Legionaries were to take the Austrian Landsturm oath and F. M. L. Durski, a Pole in the Austrian service, was placed in command. Pilsudski, having taken the oath under protest, was given the command of the first regiment.

At first both the Austrians and the Germans distrusted the movement as they stood to lose should Pilsudski achieve the national independence for which he was working. Austria moreover was hostile to any idea of Polish union and to anything which might lead to increased autonomy in Galicia. Recruiting, therefore, was forbidden. Later the Germans, realizing that the

strength of Russia would be decreased as the strength of the Polish legions was increased, allowed recruiting to take place among the Russian Poles.

The Galician situation, however, was somewhat changed by the Russian advance. On Sept. 2 Lemberg was taken by Russian troops and for the moment "the Austrian solution was at a discount." The divisions among the Galician Poles became apparent. By some, who had ties of blood and religion with the Russians, the invasion was welcomed and the new rule accepted with alacrity. The most noticeable effect of the pro-Russian sympathy is to be found in the dissolution of the E. Galician Legion, which took place in Oct. and which caused an estrangement between the Conservatives of the National Committee and the E. Galician Conservatives. Bobrinsky was appointed governor of Lemberg, his policy being that of systematic Russification.

In 1915 the Polish situation was again changed by the military campaigns. On June 22 Lemberg was retaken from the Russians and on Aug. 5 the Germans entered Warsaw: thus German power was established in Russian Poland and Austrian power reestablished in Galicia. Among the Poles themselves, in 1915, party differences seemed to decrease. In Dec. the Radical Socialist elements formed a central national committee. It was composed of the Peasants' party; the Union of Workers; the Polish Socialist party and the Club of Polish Statehood (*Stanowisko*). The aim of the league was to work for independence; it was dissolved in Feb. 1917.

By the beginning of 1916 the Polish Legion was well equipped and in June the brigades totalled 18,000. When the Polish independence parties at Warsaw asked for the nomination of Pilsudski as the commander-in-chief of a Polish army all the concessions previously granted by the Germans were withdrawn. Pilsudski then appealed to the Austrians. The Austrians' ideas with regard to Poland had undergone a slight change, and though suspicious of Pilsudski and his legionaries, the Government decided to encourage them in the hope that a union might be effected of the Polish kingdom and Galicia under Austrian protection. In July Pilsudski felt himself in a position to appeal for concessions regarding the substitution of Poles for Austrians as officers in the legion and for the use of the Polish uniform and colours. There was some delay in considering the question of these concessions and as a protest Pilsudski, together with other officers, retired. The Austrians did make and were prepared to adhere to certain concessions. They therefore negotiated with Pilsudski to withdraw his resignation. At this point, however, the German command interfered and Pilsudski was dismissed on the grounds of insubordination. In Oct. the legions were withdrawn from the front.

The Germans and Austrians were in the meantime trying to arrive at some satisfactory solution of the Polish question. The tendency of the Poles themselves was on the whole pro-Austrian, this tendency being strengthened by the union of the province of Chelm (Kholm) to Poland. The first solution proposed by the Germans was that of an independent Polish state under a Habsburg king. This state was to consist of Russian Poland, Galicia, and those parts of Posen where the Poles exceeded 65% of the population. This solution the Austrians would not accept. It was not clear how much of Poland the Germans were willing to give up, but it was clear that their sacrifice would not be so great as that of the Austrians who were to lose all Galicia. The solution proposed by the Austrians was that of a genuinely independent Poland consisting of Galicia and Russian Poland. This new Poland was to be a third co-equal state with Austria-Hungary. The German Chancellor then issued new proposals and after a Polish deputation had been sent to Berlin to discuss the terms an agreement was brought about and the result was the Decree of Independence of Nov. 5. By this decree the Polish districts "snatched from Russian power" were to form an independent state which was to have a hereditary monarchy and a constitution. The organization, training and command of the Polish army were to be settled by mutual agreement.

From the point of view of the Germans the Polish state was to be closely united to the Central Powers, "especially in military

matters." Their ultimate aim was to secure additional manpower against Russia. This settlement was not welcomed by Austria. She "had accepted unwillingly the German scheme as to Poland . . . but she hoped by her scheme of Galician autonomy so to embarrass the German settlement as to revive the Austrian solution which Berlin had rejected."¹

The independence of Poland was acknowledged on Dec. 20 by a joint Allied note and later in 1917 it was acknowledged by the Revolutionary Government in Russia.

The first attempt of the German Government to organize the new state was not successful. General von Beseler (primarily a savant and geographer), who as military governor held the chief power, issued a decree arranging for the election of 70 members of the Diet in the German sphere of occupation; eight members of the Council of State were to be chosen by these 70, whilst four others and the chairman were to be chosen by the governor-general; all resolutions of the Council of State were subject to the assent of the two governors-general. The unpopularity of this proposed organization was so great that certain modifications were introduced, and the following scheme adopted: the two Governments were to nominate immediately a council of 25, 15 from the German sphere and 10 from the Austrian; they were to elect their own chairman; they had power to regulate internal affairs and economic reconstruction and were to coöperate in the formation of a Polish army. The Council was composed eventually of 11 Conservatives, but no National Democrats, 8 of the Central party (pro-Austrians) and 6 of the Left (Socialists). It was liable to be over-ruled by von Beseler.

The powers of the Council were fairly extensive. "Education and justice were handed over to them practically without reserve; and for the first time for many years the native tongue was again heard in the schools and in the courts of law. Local representative bodies were called into being in the towns and in the country; and in Warsaw the municipality received control of all the public services, including police, prisons, posts (municipal), public sanitation and hygiene."² The finances were handed over to the Council "except in so far as the costs of the occupation" were concerned. A Minister of Political Affairs was appointed but he might hold official relations only with the Central Powers.

One of the first problems facing the new Council in 1917 was that of the economic reconstruction of the country. In his *History of the War*, John Buchan gives the following description of the condition of Poland under the German domination—"The German policy demanded a wholesale destruction and . . . Poland was methodically laid waste. . . . Only blackened ruins marked the site of villages, and since the German army ate up all supplies, famine stalked through the land. . . . The material damage can scarcely be estimated . . . all labour and industry have been swept away." In addition to the devastation, the currency was depreciated and the Customs, which might have provided revenue, were to go to Germany and Austria.

The Council was responsible for the drawing up of a constitution. A committee was formed in which all shades of opinion were represented. It was decided that a Ministry and a Senate should hold office until a genuine National Assembly could be established. As regards political matters the Council demanded that there should be a regent: that they should be given more control over local government; and that existing ordinances should be modified. These demands were not accepted by von Beseler.

The chief question which occupied the Council was that of the army. Pilsudski was attempting to raise a strong national army which would give the Council more chance of enforcing its decisions, but he was not prepared to raise it for German use.

The meeting of Council in which the political demands were formulated took place on May 1. Only unimportant concessions in education and justice were made, therefore on May 17 the Council suspended its functions, though through German intimidation it was forced to resume them on June 9. At the beginning of July three resolutions were passed: proposals for a regency,

a Cabinet and a Senate were accepted; a military oath was to be taken exacting loyalty to the Central Powers and to the future king of Poland (thus excluding a republic); and a recruiting appeal was made. These resolutions proved the submission of the Council to Germany, and in protest Pilsudski and five of his supporters resigned.

After the passing of these resolutions on July 3 the Council was discredited. It had failed to cope satisfactorily with the economic crisis and it had failed to produce a practical settlement with regard to the army. As matters stood the army could be used against the Russians but not against the Austrians or the Germans. Finally the Council was discredited by the attitude of the Austrian Poles. The Government had delayed the grant of increased autonomy to Galicia and on May 28 the resentment of the Galician Poles culminated in a conference of Polish members of the Galician Diet and of the Austrian Reichsrat, in which they declared that "the desire of the Polish nation was to have restored an independent and united Poland with access to the sea." On July 30 Polish discontent was further increased by the arrest of Pilsudski, and a month later the Council resigned.

After the failure of the Council a regency project was introduced. By this scheme there was to be a regency of three, a Cabinet and Premier and a Council of State. The Premier and the Council of State were to be chosen by the Regency Council subject to the approval of the Central Powers. The functions of the Polish authorities were limited to education, justice, public welfare, agriculture, and finance as far as it concerned the departments assigned to their care. They might legislate on matters handed over to them but the German and Austrian governors-general had the right of veto within a fortnight of the completion of the bill. The regency had no control over the army.

Such was the position of the Polish Government at the beginning of 1918. The German domination seemed more complete than it had ever been before. In 1916 the Poles could extract concessions from the Germans in view of the fact that their help was needed against the Russians. That help was no longer necessary, therefore concessions were no longer forthcoming.

When the negotiations opened at Brest Litovsk the Polish Government asked the Central Powers to admit its representatives. In spite of "weighty declarations" made at Berlin the demand was ignored and the Poles were excluded from the conference. On Feb. 9 the Treaty of Brest Litovsk was signed. As far as Poland was concerned the important clause of the Treaty was that which ceded Chelm to the Ukraine. On Aug. 17 1917 the Provisional Government of Russia had recognized Ukrainian autonomy. The Ukrainian state was composed roughly of the following territory: the western parts of the Governments of Lublin and Grodno, and the whole of the Governments of Kiev, Poltava, Kherson, Volhynia, Kharkov, Podolia, Yekaterinoslav, and Chernigov and excluded the Austrian Ukraine. On Nov. 20 1917 the Ukraine declared itself to be a republic and on Jan. 11 1918 the delegates of the Ukrainian Republic were formally recognized at Brest by the Central Powers. The territory of Chelm, which was ceded to the Ukraine at this Treaty, had been handed over to Poland by Austria only in June 1916, but its ownership had been disputed for many years and it had already before been in the possession of the Poles.

As a protest against the lack of consideration shown them at Brest the Cabinet, under Kuchazewski, resigned and the Poles issued a formal protest against the violation of their rights. This, however, made little difference to the German policy, which demanded that Poland should "completely give over all those greater hopes which might be inconvenient to Germany." This policy was emphasized later in the year when Adm. von Hintze in a speech to the Reichstag proposed an economic union with Poland on the basis of a Customs union or *Zollverein*, that is to say on the basis of free trade between Poland and Germany.

In April the Poles made a statement of their programme at the Congress at Rome. They declared their aim to be "Reunion into one independent state of all the Polish lands, including those which the Central Empires are refusing to restore to Poland and those which they are bestowing as largess on their vassals." It

¹ Nelson's *History of the War*, xviii., 123.

² Butler's *The New Europe*, p. 113.

was not, however, until the autumn that it seemed possible for them to achieve the end at which they were aiming. In Oct. it became clear that the union of the Poles no longer depended on the wishes of Vienna and Berlin, but rather on the will of the Polish people. In the same month a national Polish Diet was convoked, and in Austria all the Polish parties left the Reichsrat and formed the National Council in Cracow, until there should be "a freely elected Parliament of a United and Independent Poland." On Nov. 10 Pilsudski, having been released from Germany, arrived in Warsaw and the Council of Regency proclaimed that the German occupation had ceased to exist.

AFTER THE ARMISTICE.—The predominating figure in the evolution of the new Polish state was that of Pilsudski, who, on the abdication of the Council of Regency, took the Government of the country into his hands and succeeded in overcoming the internal and external dangers which faced the country after the German collapse.

Pilsudski was by birth a Lithuanian Pole. In 1885 as a student of medicine at Kharkov University he became connected with the Socialist movement and three years later was banished for complicity in the attempt on the life of Alexander III. though in reality he had been strongly opposed to the plot. In 1893 he returned to Poland and became one of the chief founders of the Polish Socialist party in Russian Poland. The aim of this party was the independence of Poland. In 1900 he was arrested on account of his socialistic writings but he escaped to London, after simulating madness, and two years later returned to Poland. At this time he and his associates "adhered to Socialism because they recognized in it the only powerful revolutionary and democratic force of our time and their supreme aim was, by revolutionary means to win Polish Independence."

In about 1904 Socialism in Poland became a wide popular movement. Pilsudski was responsible for organizing the military element in the new party. Primarily this took the form of the "Fighting Organization" but later systematic military instruction was given by means of Rifle Clubs, with the object of establishing a force which would be used in armed revolution against Tsarist Russia. "The war gave them their chance and at its outset they fought against Russia, for 'the fight against Tsardom had become to them a second nature.'" In 1915, however, Pilsudski stopped recruiting for his Legions, his aim being not to raise an army which was to be used for the purposes of Germany and Austria, but one which would ultimately become the army of an independent Poland. With this object in view Pilsudski created the "Polish military organization." This organization was carried on secretly and was concerned chiefly with spreading propaganda in favour of a struggle for a Poland independent both of Russia and of the Central Powers. In 1916 after conflict with the Austrian commanders Pilsudski sent in his resignation. The Austrians refused to allow his resignation but when he withdrew his brigade from the front without any previous warning, the Germans insisted upon his dismissal.

After the declaration of Polish independence Pilsudski was called upon to help in the formation of a Polish army, but this he refused to do, on the principle that a Polish army must not be formed without a true Polish national Government to direct it. In the summer of 1917 he demanded concessions from the Germans, and, in view of the feeble attitude taken up by his colleagues, he withdrew from the Council, at the same time ordering his followers in the Legions to refuse to take the oath. As a result about four-fifths of the Legion were disbanded. He was arrested subsequently by the Germans and imprisoned at Magdeburg. During his imprisonment the Polish military organization continued to develop secretly and when Pilsudski was released by the German Revolution in Nov. 1918 this organization formed the basis of the Polish army.

When Pilsudski returned to Poland in Nov. he found the country confronted with serious dangers. There was no effective Government, the Council of Regency having been dependent upon German control; the anarchy in Russia threatened to spread into Poland, and finally the danger was augmented by the 30,000 rebel German troops which were still in the country. On Nov. 14

the Council of Regency abdicated, leaving the supreme power in Pilsudski's hands. His first work was to establish an army on the foundations laid by the Polish military organisation. Through the prompt formation of the army the danger from the German troops was removed and the Bolsheviks were temporarily held back. Pilsudski's next work was to constitute a Government. "Only a Left government," it was well said, "with a programme of constructive democratic reform, could retain authority in the State. Pilsudski therefore formed the Labour Government of M. Moraczewski, and so forced the Left in this critical hour to undertake positive work instead of fruitless opposition and chaotic revolt."

At the end of 1918, therefore, Pilsudski had become the head of the Polish State. The fundamental principle which underlay his policy throughout this period was that of pushing on the Polish State in the "path of modern organic social and political life." He realized that it was social reconstruction, not social unrest, which would consolidate the new state and enable it to hold its own against the anarchic elements which threatened its existence. In the *New Europe* in June 1920 Pilsudski's achievements were thus described: "Socialist, agitator and Leader: Brigadier-General in the Austrian Army: Head of the Polish State: the changes are kaleidoscopic. He has now undoubtedly ranged behind him the great majority of the Polish people, including some of his old enemies, the National Democrats; and this success is one of the greatest tests of his ability, because Poland contains at least a score of political parties."

The first political event of importance in 1919 was the formation of a new Cabinet under M. Paderewski. At the beginning of the year there had been elements of discord between the Government at Warsaw and the Polish National Council which had been formed during the war in Paris, and of which M. Paderewski was the most prominent member. At the beginning of Jan., however, an agreement was made and when M. Moraczewski resigned his office as Premier, Paderewski succeeded him. The chief difficulties which faced the new Cabinet were that of the Bolshevik advance and the economic condition of the country of which the worst feature was famine.

At the beginning of Feb. a general election for a Constituent Assembly was held, and resulted in a victory for the non-Socialist parties, supporting Paderewski. The actual figures are reported to have been: Ministerial party 400, Socialists 80, and Jews 15.

In the summer of 1919 Paderewski, as Premier, was responsible for laying the Treaties of Peace before the Polish Parliament. The terms concerning Poland were briefly as follows:—Poland received the larger part of Posen and part of W. Prussia. A plebiscite was to determine the settlement of Masuria and Upper Silesia. Danzig was to be a free city under the protection of the League of Nations. This city was to be included within the Polish customs frontiers and its foreign relations and the protection of its citizens abroad were to be entrusted to Poland. "Poland also received the right of freely using and of developing and improving all water-ways, docks, and wharfs within the territory of the free city; and the control and administration of the Vistula river, and, subject to some restrictions, of the railway, postal and telegraph systems of Danzig." The actual details were to be settled later by a treaty between Poland and the free city. A provisional boundary was laid down between Poland and Russia, roughly corresponding to the course of the Vistula. In addition to these territorial changes, it was agreed to embody in "a treaty with the Allied and Associated Powers such provisions as may be deemed necessary by the Powers to protect the interests of inhabitants of Poland who differ from the majority of the population in race, language or religion," and also "such provisions as they may deem necessary to protect freedom of transit and equitable treatment of the commerce of other nations."

The clauses concerning Danzig, and the plebiscites for Masuria and Upper Silesia could not fail to be met with disfavour in Poland as the territories were claimed as being Polish either historically or ethnographically. Moreover, the Poles resented the suggestion that they would oppress the national minorities in the country, and felt that the inclusion of this clause was unnecessary.

In spite of these objections, the Peace Treaty was passed by the Parliament on Aug. 1 by 285 votes to 41.

At the end of Nov. a bill was drafted with proposals for a new constitution. It was proposed:—that the vote should be given to all citizens of both sexes over 21; that the National Assembly should be elected every four years; that there should be a bicameral form of Government, the Senate being quite small; that the President should be elected every seven years and that his powers should be considerable. The actual constitution was not finally drawn up, however, until March 1921.

In Dec. a political crisis took place, resulting in the resignation of M. Paderewski. It was decided by the Allied and Associated Powers that Eastern Galicia should be given autonomy for 25 years under the protection of Poland, after which settlement was to be made by plebiscite. Although the majority of the inhabitants of Eastern Galicia were Ruthenians the Poles claimed the territory and this decision of the Powers caused an outcry in Warsaw. Paderewski's explanations carried no conviction and he was forced to resign. On Dec. 15 it was announced that M. Skulski would form a Ministry.

During 1919 the Poles, with Gen. Pilsudski as their commander-in-chief, were engaged in three wars. Two of them, with the Ukrainians and the Czechoslovaks, were not of great importance. Hostilities were started with the Ukrainians on account of the disputed territories in Galicia. At the beginning of the following year a settlement was made after which the Poles and the Ukrainians joined forces to fight the Bolsheviks. The dispute with the Czechoslovaks was also on the subject of disputed territory. The duchy of Teschen, though small, is valuable because of its coking-coal and thriving industries, and for this reason both Poles and Czechs were anxious to possess it. In the summer of 1920 the dispute was settled by a decision of the Council of Ambassadors, which awarded to the Czechs the whole mining region and the chief railway running through the territory. As a result the town of Teschen is cut in two.

The third and most important war was that with the Bolsheviks. The war was caused by the German troops evacuating the eastern territories in a way which was contrary to agreement and which allowed the Bolsheviks to occupy the territory before the Polish troops could be brought up. The local population in the occupied zones appealed to the Poles for aid and, as a further advance seemed imminent, the Poles were forced to fight. The Poles have been accused of entering into this war with the Bolsheviks with imperialistic and aggressive aims. It seems clear, however, that this was not the case. The Polish army was small and was engaged in hostilities elsewhere and the financial and industrial condition of the country was such that unnecessary war would not be undertaken.

The policy of the Allies throughout 1919 was vacillating. At first direct military intervention was attempted but was given up. Later ammunition and war materials were sent to Denikin and Kolchak. Finally the "barbed-wire" policy was suggested, in which Poland was to play a leading part among the states which were to act as a barrier round Russia. This policy, however, lasted only 28 days.

In the autumn the Bolsheviks were prepared to make peace, on Poland's terms, and an armistice was suggested. M. Paderewski was advised by the Allied Powers to refuse these terms and to continue fighting. By the end of the year no further negotiations had been proposed.

During 1920 Poland "served as the centre of the resistance to the spread of Bolshevism," and her political history is very much bound up with her military history. In the spring there were some more peace negotiations, but as before these came to nothing. On April 27 a strong Polish offensive was begun, chiefly to the S. of the Pripiet marshes. The Poles advanced rapidly, capturing guns and war material, and on May 8 they entered Kiev. The Bolsheviks, owing to the defeat of Kolchak and Denikin, were now able to concentrate all their forces against Poland and in May opened a counter-offensive campaign. There was serious fighting between the Dnieper and Dvina and the Poles were forced to retreat.

In June a change of Government took place, a non-party Government being formed by M. Grabski. In view of the continued retreat of the Poles the Premier was sent to the Spa Conference to ask for help from the Allied Powers. In July Lord Curzon, as representative of the British Government, proposed negotiations on the basis of the acceptance of the provisional boundary laid down by the Peace Conference, corresponding roughly to the boundary of the Governments of the Vistula. On July 30 these terms were refused by the Bolsheviks.

In Warsaw another change took place in the Government, a War Cabinet being formed, which consisted of M. Witos, M. Daszynski, M. Grabski, M. Skulski, with Prince Sapieha as Foreign Minister. The policy of the new Cabinet was "to defend the full independence of the Polish Republic and conclude a just and lasting peace."

The Bolshevik advance had, in the meantime, been steadily continuing and by Aug. 14 they were within 12 m. of Warsaw. Even if Warsaw had fallen it is possible that the Poles might have made a successful resistance, based upon the western province of Posen, which is in many respects the most important province of the new state. The end of July and the beginning of Aug. saw further attempts for peace. On July 30 Polish officers were allowed to cross the Russian lines to conclude an armistice but they were forced to return with nothing accomplished as they were not authorized to sign the preliminaries of peace with which the Bolsheviks presented them. At the beginning of Aug. a peace conference at Minsk was arranged. As made known to Mr. Lloyd George the chief terms proposed by the Bolsheviks were: the reduction of the Polish army to 50,000, together with a small civic militia; the surrender by the Poles of all arms and war materials with the exception of those necessary for the reduced army; and the demobilization of all war industries.

Owing to Russian procrastination the peace conference was not held until Aug. 17, by which date the military situation had changed with remarkable rapidity. The Russians had advanced too fast and too far and were not prepared for any sudden counter-offensive. When Gen. Pilsudski, therefore, organized a general counter-attack the Bolshevik armies collapsed and retreated in disorder. By Aug. 21 the Poles had entered Brest Litovsk.

When, on Aug. 17, the conference opened at Minsk it was discovered that there was a difference between the terms actually offered by the Bolsheviks and those previously transmitted to Mr. Lloyd George. The terms relating to the civic militia were considerably enlarged. It was in reality to take the form of a force of armed trades-unionists, 200,000 strong and organized after the regular Soviet pattern. In short it was an attempt to foist Bolshevism on to Poland. The military situation, however, made it impossible for the Russians to enforce their terms.

In Sept. negotiations were moved to Riga, where on Oct. 12 the final treaty was signed. In the N. Poland obtained direct access to Lettland on the Dvina above Dvinsk. The Poles obtained Baranovichi, Pinsk, Kovol, Rovno and the whole extent of the Baranovichi-Rovno railway. With these boundaries the area of the new state is about 148,000 sq. m., and the population about 30 millions, but of this no accurate estimate can be yet formed. Poland ranks as the sixth state of Europe in size and population, and is by far the most important of the new states which the war has produced in eastern Europe.

In addition to the war with the Bolsheviks Poland was concerned with other foreign affairs. The treaty between Poland and Danzig was signed in 1921 but in the meantime there was "an unhappy amount of friction between the Poles, the Germans of Danzig and the British High Commissioner representing the League of Nations." The Poles in Danzig were frequently mobbed and in the summer of 1920, during the crisis in the Bolshevik war, guns and war material sent from the Allied Powers were held up in the port by the people of Danzig.

After Sept. 1920 there was friction with Lithuania. When the Bolsheviks retreated from Vilna both the Poles and the Lithuanians claimed the city, the Poles on the grounds of the language and population, the Lithuanians on the grounds of historical tradition. The Lithuanians at first took possession of

Vilna but later Zeligowski with an army of White Russians turned out the Lithuanians and established an independent Polish Government.

THE JEWISH QUESTION.—One of the most important questions to be considered by the new Polish State is that of the Jews. Numerically they form roughly one-seventh of the population. In Warsaw a third of the population are Jews: in many provincial towns four out of every five inhabitants are Jews and in some nine out of ten, and of these the vast majority are Eastern Jews who in language, religion and customs differ from the population. Their language is Yiddish, a Middle-High German dialect; for the purposes of writing, Hebrew characters are used. Their dress is peculiar to themselves and their unclean habits and low standards of conduct "are neither European nor modern." The Western Jew is the more civilized type which is generally found in western Europe, speaking the language and conforming to the habits of Western civilization.

The Eastern Jew is essentially a business or commercial man, but rarely a producer. He is usually a middleman or intermediary. In towns the majority of the shops are owned by Jews, but they are a race apart, hated and despised by the rest of the population, devoted to their religion, which is a primitive type of Judaism.

The Jews have been settled in Poland between 800 and 1,000 years so that they can hardly be considered "strangers" in the land, in fact the Slavs cannot be considered very much more native than they. It was not, however, until about 20 years ago that the present quarrel between the Jews and the Poles began. The Tsarist Government drove the Jews out of Russia but gave them exceptional advantages in Poland. These Litvaks (as they were called) openly professed themselves the partisans of Russia and founded the Jewish press which set to work openly to fight against Polish autonomy. The Poles attacked the Jews before the war by means of a national boycott, the only means by which one subject race could attack another. During and after the war the hostility to the Jews was increased by the fact that in the German occupation the Jew was the willing tool of the invader, and by the close connexion between the Jews and Bolshevism. The hostility to the Jew was marked in 1918 and 1919 by excesses in which some 200-300 have in fact been killed, but which have been enormously exaggerated by the Jewish press.

The following recommendations for the future treatment of the Jews in Poland were made by Sir Stuart Samuel in his report on his mission to Poland (Cmd. 674, 1920):—"That the Polish Government be urged to carry out the clauses of the Minority Treaty of June 28 1919, in a spirit of sympathy with its Jewish subjects. That a genuine and not a "masked" equality be accorded to the Jewish population of Poland. That all outrages against the person and property of the subject, irrespective of race or religion, should be promptly punished and the names of the delinquents published. That the Jews in E. Galicia be restored to their official positions in the same manner as non-Jews have been. That no restrictions should be placed upon the number of Jews admitted to the universities. That a decree be published declaring boycotts illegal, and ordering all publications advocating boycott to be suspended. That all prisoners in internment camps be brought to immediate trial, and that humane treatment be assured to all interned prisoners. That facilities be afforded for the introduction of new industries into Poland with a view to converting a larger proportion of the Jewish population into producers. That the British Government should assist Jews wishing to emigrate from Poland by providing facilities to proceed to countries such as Palestine, Canada, S. Africa, Algeria and S. America, or any other country desiring to receive them. That banks be established possessing the confidence of the Jewish public, so that money might be deposited therein instead of being carried on the person or concealed in dwellings. Finally, that the desirability of a secretary who understands and speaks Yiddish being added to the staff of H.M. Legation at Warsaw be considered.

Capt. Peter Wright, in his very valuable and interesting report states (Cmd. 674, 1920, pp. 17-36) that the great majority of the poor Jews are of the Eastern type and extreme orthodoxy (Chassidim). They form an immense mass of squalid and helpless poverty and Capt. Wright's only recommendation is that the richer Jews should study the condition of the poor Jews who either trade as small middlemen, as hawkers or touts, or labour as unskilled, or almost unskilled, and fill the sweating dens as sweaters or sweated when they emigrate. They are driven into all sorts of illicit and fraudulent practices and in England, in the East End of London, too large a proportion of convictions for such offence can be laid to their account. They are unfit for the modern economic world for want of education and for Western society because of their habits and want of cleanliness. They are devoted to their strange old religion but as they grow rich their piety, as the Chief Rabbi told Capt. Wright, is destroyed by wealth and they take too little interest in their poorer brethren. No one who knows Poland can be surprised at the Polish attitude or the desire of the Poles to be rid of this corrupting influence.

POLAND IN 1921.—It was still impossible in the autumn of 1921 to make any final or definite statement with regard to the boundaries of Poland; as regards Lithuania the situation remained unsettled, and it was only in Oct. that a decision favour-

able to Poland in respect to Upper Silesia resulted from the award of the League of Nations (see SILESIA).

Working on the principle of national rights it was attempted at the Peace Conference to make the boundaries of Poland conform to ethnographic divisions. A commission was appointed, under M. Cambon, which was to deal with the Polish question and submit drafted proposals to the Supreme Council. The first report of the commission concerned the western boundaries, the proposals being as follows:—"The larger part of Posen and Upper Silesia should be transferred to Poland, "leaving Germany the western, predominantly German-speaking districts of both territories." According to the German census of 1910 the Poles formed about 65% of the population in the two areas ceded to Poland. In addition Poland was to be given "the central and eastern zones of the province of West Prussia, including both banks of the lower Vistula and Danzig," though racially the latter was distinctly German. The settlement in the case of the district of Allenstein, that is to say the southern zone of E. Prussia, was to be referred to a plebiscite.

These proposals were not accepted without modification, as it was urged by Mr. Lloyd George that they were terms to which the Germans would never agree. In the first place a modification was made with regard to the territory round Marienwerder on the E. bank of the Vistula. Instead of being transferred to Poland outright this territory was to be subjected to a plebiscite. More important, however, was the change introduced in the matter of Danzig. It was decided that Danzig and the small adjacent district were to form a free city under the protection of the League of Nations. Poland received the right of freely using all the waterways, docks and wharfs and was to have the control and administration of the Vistula river. Later a third modification was made with regard to Upper Silesia, when it was decided that in this territory too there should be a plebiscite.

The results of the plebiscite in the Marienwerder and Allenstein districts were in favour of Germany, a result which was largely due to the number of Germans who were imported into the territory. The plebiscite in Upper Silesia was likewise in favour of Germany as a whole, though in many districts there was an immense Polish majority.

The southern boundary of Poland is that of Galicia. In the N.E. the boundary between Poland and Lithuania was still unsettled in 1921 and the Poles were still in possession of Vilna, the capital of Lithuania.

With regard to the eastern boundary between Poland and Russia nothing definite could be settled at the Peace Conference as there was no recognized Russian Government with which to carry on negotiations. In order to facilitate the work of the Warsaw Government in organizing local administration in the part of Russian Poland which was certain to be ceded by Russia, a provisional eastern boundary was proposed which would include all the territory which might be regarded as having "an indisputably Polish ethnic majority." All the territories to the W. of this line were to belong unconditionally to Poland, whilst the territories to the E. were to be settled by future negotiations with Russia. Roughly speaking this provisional boundary corresponded to the old boundary of the Governments of the Vistula. This provisional boundary has since become known as the "Curzon Line." When the Poles appealed, in the summer of 1920, for help against the Bolsheviks an attempt was made by the British Government to secure peace. Lord Curzon, acting on behalf of the Government, proposed the acceptance of this line as the basis of the peace terms. The Poles being unwilling to sacrifice lands which were inhabited by an incontestably Polish population would not agree to this settlement and were later, at the Treaty of Riga, able to conclude peace with the Bolsheviks on more advantageous terms.

As finally settled at Riga on Oct. 12 1920 the line of the eastern boundary is as follows: Starting from the border of Latvia the line takes a south-easterly direction to Dzisna (Dzina), thence S. passing very slightly to the W. of Dokaszyc (Dokshitsi); it passes some 30 km. W. of Minsk and, farther S., 90-95 km. E. of Pinsk; it proceeds almost due S. and then slightly S.W. to Ostrog; for

some 40 km. it continues in a south-westerly direction and then goes almost due S. again till it reaches the river Zbrucz; the boundary follows the line of this river until it reaches the Dniester, which separates Poland from Rumania.

Constitution.—Poland is a Republic. The legislative power is given to a Diet and a Senate, which are summoned, adjourned and dissolved by the President. The Diet is composed of paid members elected for five years, upon a system of proportional representation. Suffrage is universal—all who enjoy full civic rights and who are over 21 being qualified to vote, but, since voting is personal, soldiers on active service are excluded. Citizens over 25 are eligible for election to the Diet with the exception of members of the Civil Service, who cannot be elected for the district in which they hold office. The minimum age for voting in senatorial elections is 30, whilst no one under 40 is eligible for election.

Bills go to the Senate after being passed by the Diet and if no objection is raised within 30 days the bill becomes law. Amendments are considered and voted on by the Diet. With regard to finance—a budget is fixed each year for the following year; taxes and customs duties can be established only by law and a supreme court of control superintends the management of state finance.

The executive power is exercised by the President and a council of ministers who are responsible for his official actions. He is elected for seven years by the National Assembly, that is, the Diet and Senate acting together. Laws are to be signed by him and by the President of the Council and the minister concerned. The President has the supreme power in the army, except in time of war when the Minister for War is responsible for all military affairs. The President can declare war and make peace only with the consent of the Diet. He has the right of pardon.

For purposes of administration Poland is to be divided into palatinates, districts and urban and rural communes, these forming the units of local government. Economic autonomy is established by means of chambers of agriculture, commerce, industry, etc., which will together form the Supreme Economic Chamber of the Republic, the competence of which required further legislation.

Judges are nominated by the President whilst justices of the peace are popularly elected. Judges can be removed from office only in certain legal cases and following a judicial decision. All citizens are equal in the eyes of the law, protection of life, liberty and property being assured to all inhabitants. State protection is given to labour and insurance for unemployment, illness and accident is guaranteed. Roman Catholicism is the recognized religion of the country but others are allowed provided they are in accordance with the law.

Land must be cultivated from the point of view of public utility. The law is to decide to what extent citizens and independent associations may cultivate the land and exploit its mineral wealth, and in what cases the state may repurchase property to improve the value of its production.

POLAND IN 1921

Population.—It was still impossible in 1921 to give any accurate statistics with regard to the Polish population of Poland, etc., since the establishment of the new state. The following are the statistics of 1910.

Russia:—

Kingdom of Poland	9,100,000
Lithuania and Ruthenia	2,438,000
Empire	400,000
	11,938,000

Austria Hungary:—

Galicia	4,672,000
Spiz Orava, etc.	200,000
Teschen	235,000
Bukovina	36,000
Other provinces	36,000
	5,179,000

Germany:—

Posen	1,291,000
W. Prussia	604,000
E. Prussia	286,000
Silesia	1,338,000
Westphalia, etc.	580,000
	4,099,000

Different countries of Europe	100,000
Europe	21,376,000

Outside Europe:—

N. America	3,100,000
S. America	100,000
Other parts of the globe	30,000
	3,230,000

Grand total	24,606,000
-----------------------	------------

¹ A law was passed by the Diet in 1910 providing that the state should buy land from the nobles and distribute it to the Polish peasantry. Owing to the want of money the law has hitherto been in suspense. The execution of this law might eventually fall under the Chamber of Agriculture.

Economic Development.—In considering the economic development of Poland the following territories are included: the kingdom of Poland, parts of E. and W. Prussia, Posenania, Silesia and Galicia.

Agriculture.—The majority of the people of these lands, with the exception of Silesia, were engaged in agriculture before the war; the percentage being 56.6 in the kingdom of Poland, 54.1 in Posenania, 49.9 in W. Prussia, whilst in Galicia there were 71 agriculturists per square kilometre.

Arable land predominated. The most important crops were rye, oats, barley, potatoes, wheat and sugar-beet. Agriculture was most highly developed in Prussian Poland where the latest agricultural implements and scientific manures were employed. The breeding of domestic animals, especially horses, showed distinct progress before the war. In the kingdom of Poland pig-breeding was particularly encouraged. Cattle and pigs were most numerous in Posenania and W. Prussia while in Galicia the horned stock were well up to the average for Austria in general.

Of the percentage of area under forest, there was in the kingdom of Poland in 1909 some 18%, in Galicia (1912) 25%, in Posenania 19%, W. Prussia 22% and in Upper Silesia 28%. In E. and W. Prussia more than half the forest area belonged to the state, in Posenania about a third, in Silesia only about 12 per cent.

The kingdom of Poland had 17 agricultural syndicates in 1909, for selling agricultural products and buying machinery, manures, etc., the most important of these being the Central Society of Agriculture, founded in 1907. These societies were most developed in Prussian Poland, particularly in Posenania, where in 1913 there were 388 Polish agricultural societies. There were also numerous co-operative societies. Galicia also possessed agricultural, co-operative and mutual insurance societies.

Minerals.—The most important production in Galicia was that of petroleum, which was estimated, in 1914, as being 3% of the world's output and 9% of that of Europe, including Russia. The petroleum industry has attracted an abundant flow of international capital and has thus been able to adopt every device for profitable exploitation.

The chief coal-fields are those of Silesia where the production in 1911 was some 36 million tons, while that of Galicia was 13, and that of Poland 5½ million tons. Other notable mineral industries are those of iron, zinc and lead.

Manufacture.—Of industrial workers Upper Silesia possessed the largest number: 47.7% of its population were engaged in industry (1907). In the kingdom of Poland this proportion was only 15.4% (1897), in Galicia 8.8% (1900), Posenania 23.4%, W. Prussia 24.1% (1907). In the kingdom of Poland the most important industry was the textile, which occupied about 150,000 workers. Cotton manufactures were the most important, wool being second. Before the war this industry was handicapped by the high tariff charged by the Russian Government for the transport of raw material. Second in importance was the metallurgical industry, the most important manufactures being machinery, boilers, materials for bridge building, nails, wire and sheet iron. The manufacture of machinery was of considerable importance in Silesia but less developed in Galicia.

Of other industries that of the potato by-products is most important. More than a quarter of the potatoes produced in Posenania and the greater part of those of Galicia were used for the making of alcohol. Before the war the wood industry was in a poor condition owing to severe German importation duties on manufactured wood, but these duties encouraged the development of the saw-mill industry in Prussian Poland. The coastal fisheries of E. and W. Prussia are of considerable importance; likewise the pond fisheries in Poland, but fishing is generally only a subsidiary occupation.

The industry of Poland was very much influenced by the Jewish population. In the kingdom of Poland before the war nearly 15% of the population was Jewish and the following trades were more or less in their control: leather goods and the boot trade; stocking industry; manufacturing of the so-called "astrakan" caps; malt refuse breweries and small mead breweries; manufacture of paper tubes for cigarettes; and potato starch.

Towns.—The chief towns in the kingdom of Poland were Warsaw, Lodz and Sosnowice—which had over 100,000 inhabitants. The principal towns of Galicia are Lemberg (206,000), Cracow (134,000), Przemyśl (54,000) and Kolomea (44,000). In 1910 E. Prussia had five towns with a pop. of more than 20,000; Königsberg, Tilsit, Memel, Allenstein, Insterburg. There were in W. Prussia three towns with upwards of 20,000 inhabitants: Danzig, Thorn and Graudenz. In Posenania there is an unusual number of small towns, but there are only nine with more than 10,000 inhabitants; the most important are Posen (154,811 in 1910), Bromberg (70,000), Schneidemühl (27,504), Lissa (17,156). Silesia has seven towns with a pop. of more than 50,000: Breslau (537,000), Görlitz (86,000), Königs-hütte (72,000), Liegnitz (69,000), Beuthen (67,000), Gleiwitz (64,000) and Zabrze (39,000).

Communications.—Of the natural water-ways in Poland the Vistula is the most important. It has 21 tributaries, of which the total length, with that of the river itself, amounts to 7,770 kilometres. In 1864 a convention was made between Russia and Austria for the regulation of the course of the river; in Austria 64.47% of the work was completed by 1909, in Poland 39.7 per cent. Thus in Poland the Vistula is almost impossible for regular steamer traffic.

The Niemen is navigable from about halfway between Grodno and Kovno to the Prussian frontier. The Pilitsa is navigable for rafts from a point near Novo Radomsk to its junction with the Vistula, so for a small portion of the year is the Bug from the point where it first touches Poland and likewise the Narew for a considerable distance. The Oder affords the products of Silesia an outlet not only to Stettin near its mouth, but also to Berlin and Hamburg with which it is connected by an extensive system of water-ways. The Dniester is used in Galicia only for rafting timber. The chief canals are the Dnieper-Bug Canal; the Augustowo Canal, uniting the Vistula to the Niemen through the Narew; and the Bromberg Canal, uniting the Brahe to the Netze and thus the Vistula to the Oder. Of these the latter is the only canal navigable for large boats and steamers. As regards railways, in 1912 the kingdom of Poland had 2.9 km. per sq. km., the Polish provinces of Prussia had 9.27 km. and Galicia (1911) 5.24 kilometres. As the railways were constructed for the most part from a strategical point of view, industry did not benefit so much from them as it might otherwise have done. The poor railway system between Russia and Danzig was one of the causes of the decline of the trade of that port.

Trade.—With regard to commerce—the kingdom of Poland was closely attached to Russia by the protectionist system introduced in 1877 and this made trade with other countries difficult. The interchange of goods with Russia was about 2½ times greater than that with other countries. The following were the chief exports: textiles, three-quarters of which went to Russia, though trade with countries further E., notably Persia and Mongolia, was increasing; clothing and boots, which found their chief markets in Russia; horses, poultry and eggs. The chief imports of the kingdom of Poland were:—raw wool and cotton from overseas and from Russian Turkestan; iron ore and pig-iron from Russia; cattle from the steppes; and flour from Russia. In 1909 over 1.4 million q.m. of Russian flour was imported, this forming a formidable competitor to Polish milling thanks to special transport rates.

Galicia was united to the fiscal territory of Austria in 1784 and her commercial interests were generally subordinate to the will of the more powerful states of the west. The principal customer of Galicia was Germany. In 1909 the exports of Galicia to Germany amounted to 10.6 million q.m.; the imports from Germany to 6 million q.m. The chief exports were salt and petroleum and wood. The chief imports were:—textiles to the value of about 300 million francs; iron and iron goods from Germany; coal, of which 7½ million q.m. was imported in 1908.

The industry of the Polish provinces of Prussia began to decline after they were assimilated to the German hinterland. On the other hand, the protective custom tariff acted beneficially on agriculture and the trade in provisions. The principal customers of Posenania were the other states and provinces of Germany. The chief exports were sugar, alcohol and cereals. There were exported annually from 1885–1908 250,000 q.m. of wheat, 2,000,000 q.m. of rye, 410,000 q.m. of barley and 210,000 q.m. of oats. The rye was sent to Bohemia, Austrian Silesia and the kingdom of Poland, rye meal to Scandinavia, Belgium, Holland and Finland. Except for the products of local agriculture and forestry these provinces were entirely dependent on outside sources.

Coöperative credit societies developed vigorously and by 1913 they had together over 75,000 members and deposits of over 202 million francs. The Coöperative Societies' Bank, founded in 1910, formed a financial centre for the societies. With regard to savings banks, by the end of 1912 there were in Galicia 53 banks with deposits amounting to 336 million francs. In Prussian Poland coöperative societies were established on the principles of Schulze-Delitzsch and on the Raiffeisen system—after 1900 buying and selling societies were founded. The Polish credit institutions in Prussia, deriving their capital solely from Polish sources, had at disposal the sum of 498,631,000 francs.

The war left Poland in "a pitiable economic situation." The country was devastated in the first years of the war and then its resources were drained by the German occupation. The mobilization of Polish industry depends on currency stability, improved transport conditions and an abundance of available coal. The following statistics show the number of industrial workers employed before the war and on Jan. 1 1920:—

	Before the war	Jan. 1 1920	Per cent as compared with pre-war figures
Mining	28,300	36,900	130
Metallurgical	18,650	5,450	29
Metal	52,415	7,151	14
Mineral	40,900	12,200	30
Textile	168,016	38,900	23
Paper	7,000	4,000	57
Chemical	8,350	3,220	38
Tanning	8,020	2,614	32
Provisions	33,200	14,370	43
Wood	9,540
Total	374,591	124,805	34

It will be seen that the coal industry has, in spite of housing and provisioning difficulties, increased from the pre-war standard. The production of coal in Congress Poland and Galicia does not suffice to cover the requirements of the countries at present constituting the Polish State. The Reparations Committee assigned to Poland only 250,000 tons of coal per month from Silesia; and the Polish Coal Sub-Committee has granted a lump sum of 450,000 tons of coal. This lack of coal is one of the most serious hindrances to the reorganization of Polish industry.

The oil industry was not much devastated by the war, but for the first five months of 1919 the Boryslaw-Truskawiec basin and that of Bikhov were under Ukrainian administration, and oil had to be used instead of coal for working the shafts. In 1920 about half the textile industry had been mobilized and many factories started in Lodz and also in Czenstochowa, Kalisz and Bielsk. In 1919–20 the output of sugar scarcely amounted to 65% of the expected output, i.e. instead of 500,000 q.m. only 350,000 q.m. were produced. The iron foundries came to a standstill during the war and no plant was left without some essential part wanting. In July 1919 the first blast furnace started work and by the beginning of 1920 a few others were in working order. Steel production is hampered by lack of coal.

Finance.—The revenue of the Russian Treasury of the Kingdom of Poland in 1912 amounted to about 609 million francs and the expenditure amounted to about 371 million francs. From 1905 to 1912 inclusive, the excess of receipts over expenditure in the Kingdom amounted to 1,034 million francs. State officials administered the finance of 116 towns in the Kingdom of Poland. The revenue of Warsaw according to the budget of 1914 was 39 million francs. The rural communes possessed a limited autonomy. In Galicia the largest item contributed to the Austrian State was from the taxes on consumable articles and monopolies. The total receipts were 42.37 francs per inhabitant and the expenditure 26.90 francs per inhabitant. As regards the finance of Galicia as an autonomous province, in 1911 the expenditure amounted to 66 million francs, derived mainly from taxes on articles of consumption and provincial surtax on direct contributions. In the 74 autonomous districts the income amounted to 12 million francs, derived from the surtax on direct contributions and the tolls of the districts. The budget of Lemberg was over 11 million francs and that of Cracow nearly 9 million francs. In Prussian Poland the finance of the Empire was based on indirect contributions, customs yielding the largest return. In Prussia direct contributions played the most important part, the income tax producing 9 million francs in Posenania in 1911, and 7 million francs in W. Prussia. The total of the autonomous taxation of the province, districts and communes amounted to 24 francs 35c. per head in Posenania and to 30 francs 01c. in W. Prussia.

In the Kingdom of Poland the chief bank was the State Bank. In 1914 there were 38 private branches accredited to it, five branches of Petrograd large banks and five branches of the Riga Bank of Commerce. In Galicia the most important were the Austro-Hungarian Bank, with 13 Galician branches and 20 branches of Vienna and Tehek Banks. Branches of the Reichsbank and of large German Banks protected the German element in Russian Poland. In addition to these there were joint stock banks for credit for short periods. In the Kingdom of Poland there were nine; the deposits amounted to over 296 million francs in 1914. In Galicia the Mortgage Bank was the largest joint stock bank, which in 1912 discounted bills of exchange for 178 million francs. In Prussian Poland the most important was the Bank of the Federation of Coöperative Societies, which had a capital of 29 million francs in 1916. Credit for long periods depended, in the Kingdom of Poland, on the Land Credit Society and the Peasants' Bank; in Galicia, on the Land Credit Society and the Commission of Rentengüter, and in Prussian Poland chiefly on coöperative credit societies.

Finally Poland was in a crippled condition financially. The mark which was at 40 to the pound sterling in 1919, touched a new low record on June 28, 1921—namely 6,400 to the pound, and after that fell for two days to 9,000 to the pound. This rate of exchange prevented Poland from trading internationally and consequently hindered her economic reconstruction. On July 30 the Polish budget for 1921, the first real balancing of expenditure and revenue produced by any Polish finance minister, was presented to the Diet and showed a deficit of 80,000,000,000 marks (the exchange on that day being about 8,000 to the £) for Russian and Austrian Poland without the Polish part of the Austrian duchy of Teschen. The former Prussian provinces which only came under the Ministry of Finance on Sept. 1 1921 have a surplus of 6,000,000,000 marks which reduces its national deficit to 14,000,000,000 marks.

The Ministry of War was responsible for 30% of the expenditure, railways for 21% of the expenditure and food supplies for some 10%. But it may be said that the existing low rate of exchange gave no real indication of the prosperity of the country. Polish indebtedness was not great (about £6,600,000 at the exchange of July 30 1921), the productive capacity of the country was increasing, and the harvest prospects were excellent.

REFERENCES.—The one indispensable introduction to things Polish for English readers is the little volume entitled *Poland* in the Home University Library by Prof. Alison Phillips. In that admirable summary there are but two lacunae. The Exodus to Paris after 1830 and the Jewish question are not adequately treated, but it

contains a good bibliography for beginners, to which there are only a few additions to be made:—Geoffrey Drage, "Pre-war Statistics of Poland and Lithuania," published in the *Journal of the Royal Statistical Society* (March 1918); Bruce Boswell, *Poland and the Poles* (1920); Ralph Butler, *The New Eastern Europe* (1919); Erasmus Pils, *Poland* (1916); Askenazy, *Danzig and Poland*; Bass, *The Poles Tangle* (1921); Mandell House Seymour, *What Really Happened at Paris* (1921); Pernot, *L'épreuve de la Pologne*; Report by Sir Stuart Samuel on his Mission to Poland (Cmd. 674), 1920. (G. Dr.)

POLICE (United States).—An interesting recent development as regards police in the United States has been the establishment in certain states of a state police, sometimes called constabulary. This body acts under state rather than local authority, is usually organized on a military basis, is widely distributed for patrol duty, but can be quickly mobilized for emergencies. Such forces are of special service for protecting life and property in country districts, made accessible to robbers and assassins by the introduction of the automobile. Since the adoption of national prohibition much of their time has been spent in suppressing illegal liquor traffic.

The largest state police force is that of Pennsylvania, consisting in 1920 of 415 officers and men. It was organized in 1905 somewhat after the model of the Canadian Northwest police. It is composed of five troops with posts in different parts of the state. Detachments are sent out to the 40 stations and from the stations small patrols operate in every direction. The posts and stations are in constant communication, and help can be rushed immediately to any point. They are empowered to make arrests for any violation of the law; at the same time they act as fish and game wardens and as fire patrols. When practicable they coöperate with the local authorities in preserving order. In some states their powers are somewhat restricted; in New York they cannot enter a city to suppress a riot unless so ordered by the governor or on request of the mayor with the approval of the governor. But in any state they may pursue a criminal and arrest him anywhere. In Pennsylvania applicants for appointment who have served in the army, navy or militia are given preference. The recruit serves a probation period of four months and makes a study of the state laws. The period of enlistment is two years. Another type of state police is seen in South Dakota, where the sheriffs and deputy-sheriffs form a state constabulary "for the purpose of detecting crime, apprehending criminals, suppressing riots, preventing affrays, and preserving and enforcing law and order throughout the state." In Idaho all state, county and municipal officers form a state constabulary under the direct control of the commissioner of the department of law enforcement. A third type is seen in the Massachusetts District Police, consisting of a detective and an inspection department. Appointments are made by the governor and his council. At the governor's command they suppress disorder anywhere in the state. They do not maintain a patrol. In 1920 a state police, or constabulary, was maintained in 12 states: Massachusetts, Texas, Connecticut, Pennsylvania, Nevada, New York, South Dakota, Michigan, Idaho, New Mexico, Tennessee, and West Virginia. At that time several other states were considering the establishment of such forces.

A special committee on state and metropolitan police, appointed by the American Institute of Criminal Law and Criminology, in a report submitted in 1920 urged active coöperation "in educating the people, and especially the Legislatures of their respective states, with respect to the nature, methods, and value of a state police force."

See this committee's report, "Metropolitan and State Police," in the *Journal of the American Institute of Criminal Law and Criminology*, vol. xi., No. 3 (Nov. 1920). An excellent account of the largest and best organized of the state police forces is given by Katherine Mayo in *Justice to All: The Story of the Pennsylvania State Police* (1917), with an introduction by Theodore Roosevelt.

POLLIO, ALBERTO (1852–1914), Italian general, was born at Caserta on April 21 1852. Before he was nine years old he entered the Naples military college, and he received his commission as a sub-lieutenant of artillery in April 1870. He served with distinction in various posts, and in June 1908 he was appointed chief of the Italian general staff, a position which he retained till his sudden death on July 1 1914. Pollio

acquired a wide reputation as a writer on military subject, his chief works being on Waterloo and Custozza. Both these books were translated into various languages.

POOR LAW, in the United Kingdom (see 22.74).—During the decade following the publication of the Royal Commission's Reports in 1909 the English Poor Law system underwent some minor administrative reforms. The commissioners had laid bare many crying scandals, and their reasoned indictment of the whole system aroused immediate and wide-spread interest. An agitation was set on foot, and actively prosecuted for several years by the partisans of the Minority Report, who demanded the complete abolition of the Poor Law. Many M.P.'s, irrespective of party, were pledged to this, and the public generally was prepared for drastic legislation. It was expected that the Government would presently take the matter up, when the outbreak of the World War in 1914 shelved the question. Meanwhile the Reports and the agitation begun in 1910 could not be entirely ignored by the Poor Law authorities themselves. Mr. John Burns, the President of the Local Government Board, though a staunch defender of the Poor Law, was bound to admit that some amendments were necessary. But these, he claimed, could be carried out by his own department. What was wanted was not, as he put it, "reform by revolution, but revolution by reform in administration." The administrative revolution, however, did not produce any startling changes. A new Relief Regulation Order was issued, which did a little to improve the administration of outdoor relief, but left the fundamental objections untouched. Another Order (Poor Law Institutions Order 1913) was designed to consolidate the regulations governing indoor relief. This, too, effected slight improvements in classification, the quality of the nursing service, the paupers' dietaries and so on. It also insisted on the removal of children over three years of age from the general mixed workhouse into separate institutions or quarters. But many of the boards of guardians were apathetic, or openly defiant of the central authority, and a steady pressure was required to reduce the numbers of these children, whose condition had been shown by the Royal Commission in 1909 to be peculiarly scandalous. During the war this pressure was relaxed, and in 1921 there was still a residue of children between 3 and 16 years of age (besides the infants under 3) living in the general workhouse wards. In 1911 a Boarding-out Order emphasized the need of closer supervision and more adequate allowances for the pauper children lodged in private houses with "foster-parents." There was also an attempt made to deal with the problem of vagrancy in London, by putting all the casual wards of the Metropolis under the control of the Metropolitan Asylums Board, coöperating with the police and various philanthropic agencies. And rather late in the rest of the country most of the boards of guardians combined in county vagrancy committees, for the better co-ordination of their treatment of the tramps. "Way-tickets" and bread-stations were established, a number of casual wards were closed, and expenses were pooled. But these reforms scarcely amounted to a revolution, either in their conception or in their effects.

Of the later developments only two are of any importance. The Representation of the People Act 1917 removed the disfranchisement which had been one of the chief stigmata of pauperism. Hitherto the receipt of parish relief (other than medical relief only) "within the twelve months next preceding the last day of July in each year" had disqualified a man or woman from being registered as a voter. Now anyone may vote, provided he is not actually an inmate of a Poor Law institution at the moment of the election. In 1919 the Local Government Board ceased to exist, and was succeeded as the central Poor Law authority by the newly created Ministry of Health. This change made no outward difference, but it was generally taken to foreshadow a thorough reform of the Poor Law system, and the Ministry of Health Act 1919, sect. 3 (3), actually contains the significant words: "in the event of provision being made by Act of Parliament . . . for the revision of the law relating to the relief of the poor and the distribution amongst

other authorities of the powers exercisable by boards of guardians." The removal of the pauper disfranchisement was in harmony with the growing democratic spirit of the time, and reveals clearly the enormous change in thought since the setting-up of the "New Poor Law" in 1834. The same softening tendency appears also in the trivial, but significant, alteration of the name of the workhouse: the workhouse is now officially known as "the institution," though the word "workhouse" must be retained for certain legal purposes.

Meantime, a different sort of reform was proceeding from outside the Poor Law, by the increasing inroads of the local authorities into the field of the guardians. On the removal of the "pauper disqualification" in 1911 many thousands of the destitute aged became entitled to old-age pensions and so passed out of the Poor Law. Similarly the National Health Insurance Act took a vast number of patients, or potential patients, from the Poor Law medical service. And later Acts, empowering the local health authorities to set up maternity and infant clinics, to provide midwifery, to supply milk to expectant and nursing mothers, to treat venereal disease or tuberculosis, have still further diminished the scope of the Poor Law. All this, however, desirable as it might be from the point of view of social progress, could hardly be regarded as "Poor Law reform" save in an ironical sense. In point of fact, it served to reinforce more and more strongly one of the principal charges made by the Royal Commission in 1909. For it meant in practically every department an increase of administrative disorder—overlapping, multiplication of machinery and waste. In the case of every class of the pauper host, infants, children of school age, the sick, the feeble-minded, the aged, the able-bodied, there is now at least one, and generally more than one, other authority set up as a rival to the board of guardians. There is little, if any, co-ordination between the work of the medley of public bodies engaged in giving various forms of assistance out of the rates and taxes. They are in many cases dealing on different lines, and for different reasons, with different members of the same family. So far as the Poor Law Guardians are concerned, it is often a mere matter of chance whether it is they or the local health or lunacy or education authority who become responsible for a sick or feeble-minded person or a school-child. And as regards the aged, it was found that at the beginning of 1920, out of a total of 46,846 paupers over 70 in England and Wales, no less than 9,345 were old-age pensioners, two-thirds of them receiving outdoor relief and the other third in institutions.

When, in the latter period of the World War, public attention was directed to the problems of social reform that would have to be solved after the peace, this question of "public assistance" inevitably bulked large. In July 1917 the Ministry of Reconstruction appointed a "Local Government Committee" to consider and report upon "the steps to be taken to secure the better co-ordination of public assistance in England and Wales and upon such other matters affecting the system of Local Government as may from time to time be referred to it." Its report—popularly known as the Maclean Report, from the name of the chairman, Sir Donald Maclean, M.P.—was presented at the end of 1917. Subject to reservations by certain members of the committee, it was unanimous on the main point. The existence side by side, it declared, of the boards of guardians on the one hand, and the county, municipal and other health and education authorities on the other, produced both overlapping functions and areas and conflicting principles of administration.

"The resulting confusion has been aggravated by the growth of popular prejudice against the Poor Law—a prejudice which does more than justice to the devoted work of the Guardians, and the conspicuous improvement in poor-law administration, especially in respect of the children and the sick. For the last decade Parliament has been unwilling to entrust the Boards of Guardians with new functions, and the provision for new services has had to be made by other Local Authorities—in some cases new Local Authorities—often to the increase of the confusion and overlapping. Further, the classification by institutions and the specialized treatment of recipients of assistance almost necessarily involve an enlargement of existing areas of administration."

therefore, recommended the abolition of the boards of guardians and the Poor Law unions. The scheme was summarized as follows:—

1. All functions of the boards of guardians should be transferred to county boroughs and boroughs with populations exceeding 50,000.
2. Provision for all the sick and infirm (including the aged, mental care, and maternity and infancy) should be made by local authorities under the Public Health Acts suitably extended.
3. The county or any urban district with over 20,000, or any urban district with over 10,000 or any urban district with over 5,000, should be an autonomous health authority, with such reservations as may be desirable.
4. Mental deficiency should be dealt with by the local education authority.
5. Every county or county borough (or borough or urban district with population over 50,000) should set up: (i.) a prevention of unemployment and training committee (on the lines of the Education Committee, and including representatives of employers and educationalists); (ii.) a home assistance committee (on the lines of the Education Committee) to enquire into the economic circumstances of applicants for public assistance, to supervise them, to administer allowances in the home, to recover expenses of maintenance for applicants, and to keep a private register of all such applicants and families and of the assistance given.
6. Every county or county borough (or borough or urban district with population over 50,000) should appoint committees for districts or for groups of districts, to which various functions of the home assistance committee and the prevention of unemployment committee should be delegated. Such district committees would consist of: (a) members of the county council; (b) borough or district council; (c) persons experienced in the work to be done.
7. The London County Council should have a special scheme, in which the functions of the home assistance committee and the prevention of unemployment committee should be divided between the London County Council and the metropolitan borough councils. The borough councils would appoint home assistance committees, and would also be responsible for valuation and registration of births and deaths. The London County Council would, through its appropriate committees, exercise the functions transferred. It would also appoint a central assistance committee, which would lay down a policy and rules of administration for the home assistance committees in the metropolitan boroughs.
8. Poor Law officials should be transferred to the local authorities (subject to the local authorities' agreement), and cost of any pecuniary loss incurred by the change.
9. The cost of all functions transferred should fall on the authority (the county, county borough, borough or urban district) in London mainly on the county, but partly on the metropolitan boroughs.

Scotland, of course, was outside the committee's reference, but if their proposals were adopted, a Scottish scheme of similar lines would undoubtedly follow.

These recommendations were an endorsement of the principles advocated by the Royal Commission in 1909. The Maclean Report was, indeed, a compromise between the majority and minority of the Royal Commission, though leaning heavily to the side of the minority, who, unlike the majority, had insisted above all on the abolition of the *ad-hoc* destitute authority. And the importance of the new recommendations was enhanced by the fact that they marked the actual reconciliation of the two parties, since Lord George Hamilton, Sir Samuel Provis, who had signed the Majority Report in 1909, and Mrs. Sidney Webb, who had signed the Minority Report, were unanimous on the Maclean Committee. The Government eventually pledged itself to legislate on the lines of Maclean's recommendations at the first opportunity. But no opportunity had been found by the session of 1921.

The Poor Law system, therefore, then remained still in the state in which it was in 1834, when the famous "principles" were established, that relief should not be offered to able-bodied persons and dependents except in a well-regulated workhouse; and, that the lot of the able-bodied should be made "less eligible" than that of the independent labourer of the lowest class. These principles had already worn very thin by the beginning of the century, and the Royal Commission in its investigations from 1909 discovered a wide-spread laxity. Nevertheless, what the administration was, or is, lax or strict, its character is determined by the fact that the Poor Law deals with the destitute. It is true that the guardians are entitled to interpret "destitute" fairly broadly—to treat it, in fact, as meaning "necessitous"—but in practice this amounts to little. Generally speaking, relief is given to those who are in a grave state of want. That fact, and its natural consequences, especially in the domain of public health

been increasingly emphasized in recent years. There is no doubt that it has been one of the chief reasons why public opinion has favoured the sapping of the Poor Law by local authorities, who are under no such restriction and are better able to apply preventive rather than palliative treatment. But the absence of public assistance by these other bodies, while adding to the confusion, still leaves a huge volume of pauperism and a huge expenditure by the Poor Law guardians.

The following figures show the total number of persons in England and Wales in receipt of Poor Law relief of all kinds in each year:—

1900	803,247	1917	37,327
1905	924,630	1918	36,785
1910	935,738	1919	34,617
1914	761,578	1920	26,418
1915	762,060	1921	3,667
1916	684,549		

None of these figures of course represents the cost of pauperism in any one year, for they only relate to one allowance must be made for many other individuals—amounting to several hundreds of thousands—who will receive relief at one time or another during the twelve months. The figures do not, however, afford an accurate basis for tracing the movements of pauperism. It will be seen that between 1910 and 1914 there is a large fall. This is mainly due to the causes noted above—the removal of a large number of the aged and of the sick from the Poor Law. The declaration of war in Aug. 1914 there was a sharp rise in pauperism, owing to the rapid and widespread dislocation of industry. In three weeks of the outbreak of hostilities the total of persons in receipt of relief was over 40,000 higher than that for the corresponding date in 1913, and a month later it had risen by another 10,000. Very soon, however, there began an equally rapid recovery. With the absorption of men into the army or munition work and the influx of the women into industry, pauperism declined month by month. Many of the workhouses and infirmaries were taken over by the War Office for military use, their inmates being moved to other buildings or boarded out in neighbouring unions. The volume of pauperism continued to fall progressively till the end of the war, when the influence of such causes as enlistment, the unsatisfied demand for labour of all sorts, both of men and women, the generally depressed wages, and the steady income drawn from separation allowances and pensions by poor people whose earnings had previously been precarious or inadequate. Nevertheless, there was a slight rise in the Armistice in Nov. 1918 the figures began to mount again. Demobilization brought in its train a renewal of unemployment, together with industrial disputes and reduced earnings. Through 1919 and 1920 the rise continued until, at the beginning of 1921, when the whole country was involved in a serious trade depression, the total was approaching the pre-war level.

The movement of Poor Law expenditure during the first twenty years of the 20th century shows little fluctuation; it increased continuously, as the following figures indicate:

Total Expenditure on all Poor Law Services in England and Wales			
1900	£11,567,649	1917	£16,187,744
1905	13,851,981	1918	17,039,623
1910	14,849,584	1919	18,423,883
1915	15,804,073	1920	23,501,241
1916	16,085,586		

The reason for the paradoxical increase of expenditure on a decreasing number of persons during the war is, of course, to be found in the rising cost of maintenance, including food, fuel, medicine, salaries and so on. The average cost of maintaining a pauper in the general workhouse before the war was 13s. 8d. per week in London and 10s. 3d. elsewhere (1910). In 1918 it was 18s. 5d. in London and 20s. 3d. elsewhere, whilst the weekly cost of maintenance in the infirmary was 37s. 6d. in London and 30s. 4d. elsewhere. In 1919-20 the cost had mounted to 24s. 5d. in London and 25s. 6d. elsewhere for maintenance in the workhouse, and to 46s. 7d. in London and 40s. 3d. elsewhere for maintenance in the infirmary. In Scotland the figures, both of persons relieved and of expenditure, pursue much the same course, though they are naturally much smaller since the population of Scotland is less than one-seventh of that of England and Wales. In May 1920 the total number of legal poor of all classes in Scotland was 87,868. The majority were on outdoor relief, 16,175 were insane, maintained in asylums, lunatic wards or private dwellings. Of the sane, between 8,000 and 9,000 (including nearly 800 children) were in the poorhouses. The Scottish Poor Law expenditure for 1918-9 amounted to £1,667,536 and for 1919-20 to £2,093,523. The weekly cost of maintenance in the poorhouses in 1920 averaged about 23s per head. (C. M. L.)

POPPER, DAVID (1846-1913), Bohemian violoncellist (see 22.91), died in 1913.

PORTER, BENJAMIN CURTIS (1843-1908), American painter (see 22.113), died in New York City April 2 1908.

PORTER, HORACE (1837-1921), American diplomatist and soldier (see 22.116), died in New York City May 29 1921.

PORTO RICO (see 22.124).—Important developments in the affairs of Porto Rico—political, economic, social—took place in the decade 1910-20. Politically, the organic law was first amended and later materially changed. Economically, the agriculture and commerce of the island underwent notable increase. Socially, there was progress in the betterment of living conditions, in the spread of elementary education and in the reduction of poverty and disease. The Act of Congress approved April 12 1900 (the Foraker Act), under which the island had been administered for the first decade of its existence under the American flag, was amended by the Act of Congress approved July 15 1900 (the Olmsted Act). In so far as supervised by the United States, Porto Rican affairs were placed under the jurisdiction of an executive department to be designated by the president, the War Department being subsequently designated. To prevent recurrent deadlocks over the insular budget, provision was made that if the legislature failed to pass the appropriation bill for an ensuing fiscal year, the sums authorized for the current year should be deemed to have been appropriated and might be lawfully expended. Far more thorough-going were the changes effected by the passage of the Act of Congress approved March 2 1917 (the Jones Act). By its provisions citizens of Porto Rico are deemed and held to be citizens of the United States.

Six executive departments are constituted: justice, finance, interior, education, agriculture and labor, and health. The governor, the attorney-general and the commissioner of education are appointed by the President of the United States, subject to the approval of the U.S. Senate; the heads of the remaining departments by the governor of Porto Rico subject to the approval of the insular Senate. The law-making power is vested in a legislature consisting of a senate of 10 members and a house of representatives of 30 members, all elected by manhood suffrage for a term of four years. Acts of the legislature may be vetoed by the governor; but his veto may be overridden by a two-thirds vote. The President of the United States may nevertheless interpose a final veto. Matters relating to franchises and concessions are vested in a public service commission consisting of the heads of the executive departments, the auditor, and two elected commissioners. A resident commissioner to the United States, paid by the Federal Government, is elected by popular vote for a term of four years; he represents the island in the House of Representatives, with voice but without vote, and is recognized by all departments in Washington.

The economic experience of the years 1910-20 was the increased and more profitable production of sugar, tobacco, coffee and fruits, consequent in the first instance upon duty-free access to the American market, and aided by the completion of insular projects of irrigation. The increase of exports was accompanied by larger imports, by a reversal of the island's adverse trade balance, and by an appreciable though unequal diffusion of gain among the island's population, the growers of sugar and tobacco being specially benefited. The commerce of the island trebled in the decade, the combined value of imports and exports rising from \$78,705,364 in 1911, to \$247,199,983 in 1920. This amazing growth was uneven. The activity of 1911-2 was followed by reaction in 1913, accentuated by the dislocations consequent upon the outbreak of the World War. War demand for the island's staples made itself sharply felt in 1916-7 with some arrest in 1918-9. In 1920 came sensational developments, exports rising from \$79,496,040 in the preceding year to \$150,811,449, and imports from \$62,400,360 to \$96,388,534. The factors directly responsible were the world's runaway markets in sugar and to a less absolute degree in tobacco and coffee. Sugar exports in tonnage were actually less in 1920 than in 1916 and 1917; the price per ton rising from \$5.81 in 1911, to \$136.77 in 1919, and to \$235.88 in 1920.

The visible trade balance in favour of the island rose from a previous maximum of \$27,780,417 (1916) to \$54,422,915 in 1920. The great bulk of this trade, 90% in 1920, was with the United States.

There was marked improvement during the decade in the island's material equipment. New schoolhouses were erected, and additional roads and bridges constructed. Even the remoter towns of the interior had in 1920 waterworks and electric-lighting plants, made possible through loans from the insular treasury. The increase in private wealth was reflected in the erection of many attractive residences, while the development of commerce and agriculture stimulated the extension of bank and transportation facilities. The basis of the insular revenue system remained the measure put into

operation with the establishment of civil government under the American flag (the Hollander law), as modified and adapted to meet changing conditions. Ordinary expenditures for the fiscal year 1920 were \$7,258,970.57, as compared with \$3,685,613 in 1911. The total assessed valuation of all property for purposes of taxation in 1920 was \$264,235,686, as compared with \$133,817,931 in 1911.

The pop. of the island in 1920, despite appreciable emigration to the United States and Santo Domingo, was 1,200,809 (an increase of 181,797 in the decade), with a density distribution of 378.4 per square mile. In consequence of this continued growth, education and health remain grave problems. The total enrolment in all schools supported by public funds was 184,991. Of the 228,829 children of compulsory school age (8-14 years) only 61% attended school. The death-rate for 1920 was 23.33 per 1,000 inhabitants as compared with 24.97 in 1911. But in 1920, tuberculosis, malaria and uncinariasis (hookworm), together with infant mortality, still accounted for 60% of the total death-rate. The enquiries of a commission sent by the Rockefeller Foundation upon the request of the insular authorities confirmed the opinion that about 90% of the people of the island were infected with uncinariasis. "Our population is one of the densest on earth," the insular commissioner of health, himself a distinguished Porto Rican, wrote in 1920. "More than 70% are in the country, badly housed and fed, ill in health and ignorant of the first principles of hygiene. Until the people have learned to preserve and protect their health and have more ample means to provide better houses and food so as to reduce their miseries, no positive result, no recompense for all our efforts, can be obtained."

The governors were (George R. Colton, 1909-13; Arthur Yager, 1913-21; E. M. Reily, 1921- (J. H. Ho.)

PORTUGAL (see 22.134).—The effects of the Portuguese Revolution of Oct. 1910 fell most heavily on the poor of the country districts, who suffered from the loss of charities sustained by the expelled religious bodies and of the care of the sisters of charity, and from the exile of many of the richest families and the transference of capital abroad. In consequence, emigration in the years preceding the World War increased to an unprecedented extent, rising from 6.83 per 1,000 in 1910 to 14.85 per 1,000 in 1912. In one district, that of Braganza (Bragança), it rose to 6% of the population. In the towns unrest was less passive and discontent with the working of the Republic was prevalent; lavish promises had aroused impossible hopes among the people, and by many the Republic was regarded as but a first step towards a more Radical workmen's republic. Socialism and syndicalism developed rapidly. The right to strike at 24 hours' notice, conceded on Dec. 7 1910, was followed by strikes of all kinds, including several serious railway strikes. The disorders culminated in the demonstration against Parliament on Aug. 2 1911 and the general strike at Lisbon on Jan. 31 1912, when the city was placed under martial law and over 1,000 workmen suspected of syndicalism were arrested. The new governing class, largely composed of professional men, chiefly lawyers and journalists, had not the necessary authority to prevent excess.

The Provisional Government of the Republic consisted of Dr. Theophilo Braga, President, Dr. Antonio José de Almeida (Home Affairs), Dr. Afonso Costa (Justice), Col. Corrêa Barreto (War), Dr. Amaro Azevedo Gomes (Marine), Dr. Bernardino Machado (Foreign Affairs), Dr. Basilio Telles and, later, Dr. José Relvas (Finance), Dr. Antonio Luiz Gomes and, later, Dr. Brito Camacho (Public Works). It lasted till Aug. 24 1911.

The Constitution.—On March 18 1911 the new electoral law came into force. It gave the vote to all Portuguese over 21 years of age who could read or write, including priests and officers of the army or navy, but excluding naturalized Portuguese, officers on the active list and persons proscribed politically. Lisbon and Oporto (voting on the proportional system) were to return ten deputies each, the other districts four and the colonies one each. By a modification of Jan. 11 1915 Lisbon received 20 deputies, Oporto 10, the remaining constituencies between 1 and 4 each. By a decree of March 11 1918 universal suffrage for all citizens over 21 was established, but illiterates (75% of the pop.) were again disfranchised in 1910. By the law of 1918 the number of deputies was reduced to 155, returned by 51 constituencies, of which Lisbon returned 14, Oporto 6. The representation in the Senate, consisting of 77 members, was made regional and professional. By a decree of April 26 1918 soldiers and sailors on active service were allowed to vote. In the elections held on May 28 1911 many of the candidates were nominated by the authorities

without opposition and, even where there was an election (in 28 out of 30 districts), the Government candidates were returned without difficulty, no Royalists offering themselves.

The Constitutional Assembly was opened on June 19 1911 and a decree was passed declaring the monarchy abolished and the House of Braganza forever banished from Portugal. On Aug. 20 the new constitution was voted. It provided for two Chambers, that of the Deputies, consisting of 163 members to be elected every three years, and the Senate, consisting of 77 members. The President of the Republic was to be elected by both chambers for four years and could not be reelected. His salary was fixed at £3,600, with £1,200 for expenses. On Feb. 19 1920 he was given the right to dissolve parliament, after consulting a special council appointed for this purpose.

The first President under the new constitution was Dr. Manuel de Arriaga (born in 1840, at Horta, in the Azores), who, on Aug. 24 defeated the Radical candidate, Dr. Bernardino Machado, by 121 votes to 86, the Conservative candidate, Senhor Braamcamp Freire, having withdrawn. The members of the first Constitutional Ministry were: Dr. João Chagas, premier and minister of Home Affairs; Dr. Augusto de Vasconcellos (Foreign Affairs); Dr. Duarte Leite (Finance); Gen. Pimenta de Castro (War); Senhor João de Meneses (Marine); Dr. Celestino de Almeida (Colonies); Dr. Diogo Tavares de Mello (Justice); Dr. Sidonio Paes (Public Works). The Government was opposed by the Radicals under Dr. Afonso Costa and faintly supported by the other groups—the Evolutionist followers of Dr. Almeida, the Unionist followers of Dr. Brito Camacho and the Independents. One of the first measures was to vote the payment to each deputy of 175. for each sitting of the assembly.

Church and State.—The anti-clerical policy of the Provisional Government had entailed serious difficulties. The bishops signed a pastoral letter of protest and on March 8 1911 the bishop of Oporto was removed from his see, with a pension of £240. The religious orders had been expelled by the decree of Oct. 8 1910, their property confiscated and the convents closed. By that of Oct. 22 the teaching of religion in the primary schools was forbidden. Marriage of priests became legal. The decree of separation between Church and State was drawn up, under the date of April 20 1911, by Dr. Afonso Costa, then Minister of Justice. It granted full liberty of conscience to all Portuguese citizens. The Roman Catholic religion ceased to be that of the State, which recognized all creeds as of equal authority, making no payment for their support. Among other proscriptions, public worship was to be open to the public and was held to include religious instruction, public or private. The congregation might only contribute to the expenses of their worship through the *miseri-córdias* or other Portuguese charitable institutions. The churches were declared inalienable without the consent of the Minister of Justice and might be expropriated at any time. Local authorities were given full power to restrict or forbid processions, funerals or other external acts of worship. An inventory was to be taken (June-Sept. 1911) of all Church property, including churches and cathedrals, which became the property of the State. The clergy were granted a salary under certain conditions and all ecclesiastical property was made liable to taxation. The priests were forbidden to wear the cassock except at services. No foreigner or naturalized Portuguese might take part in any service except in the case of international agreement or ancient custom. Papal edicts might not be promulgated in Portugal without the consent of the Government.

This decree, in a country where over 90% of the inhabitants were Roman Catholic, was considered to be the subjection of the Church to the State rather than its separation, and contributed towards alienating the north of Portugal from the Republic. The patriarch of Lisbon and the bishop of Guarda published a pastoral letter forbidding the clergy to accept salaries from the State. For consistent opposition to the law of separation the bishop of Guarda and the patriarch of Lisbon were banished from their dioceses for two years.

The value of the Church property confiscated was £6,000,000. Owing to official protests on behalf of some of the foreign congregations

gations a promise was made to revise the law of separation, a promise only partially redeemed in 1918. Claims for compensation were referred to the Hague Tribunal by an agreement signed July 31 1913 by Great Britain, France and Spain, the only countries which accepted arbitration. The claims, including those of Italy, Belgium and Germany, amounted to £2,000,000. By the award given Sept. 5 1920 Portugal was condemned to pay £21,800 to Great Britain and £80,000 to France.

After the promulgation of the law of separation, and the Pope's encyclical of May 23 1911, *Jamdudum in Lusitania*, relations between Portugal and the Vatican were broken off, and the Portuguese Legation at the Vatican was suppressed July 10 1913. The law was extended in Nov. 1913 to the Portuguese colonies, where the discouragement of Portuguese missions later gave rise to serious fears of the denationalization of the colonies through the activity of foreign missionaries. When Paes subsequently became president, one of his first acts was to redress some of the grievances suffered under the law of separation, and, by a decree of Dec. 22 1917, banishment imposed on the priests was annulled and the Cardinal Patriarch returned to Lisbon. In May 1918 conversations between the Papal Nuncio and the Portuguese Minister at Madrid resulted in a visit of the former to Portugal and he was received by President Paes, who informed him of the intention of the Government to send a Portuguese representative to the Vatican. Monsignor Locatelli was appointed Papal Nuncio in Portugal in April 1919. Relations with the Vatican were maintained after President Paes' death, and in 1919, and again in 1920, the Pope wrote Cardinal Mendes Bello and the Portuguese prelates congratulating them on the improved religious conditions.

The Royalist Invasions.—The main event of Senhor Chagas' premiership was the first Royalist invasion, commanded by Capt. Henrique Mitchell Paiva Couceiro. Small Royalist risings had been suppressed during the summer of 1911, but Capt. Couceiro still threatened the northern frontier. Representations were made by the Republic to the Spanish Government, which was itself suffering from the action of Portuguese Republicans in Spain. The Spanish authorities seized 4 Krupp guns and 1,000 rifles at Orense, and the German steamer "Gemma," with rifles and ammunition, was detained at Corcubión. The steamers, "Foam Queen" and "Arizona," with war material, ostensibly bound for Bahia Blanca, were detained by the customs authorities of London and Barrow in August. Couceiro crossed the frontier on Oct. 3 at the head of about 1,000 men, not a quarter of whom were armed with rifles. He advanced in the direction of Braganza and took the small town of Vinhaes, but evacuated it on Oct. 6 and, after maintaining himself for a fortnight in the hills, recrossed the frontier. A Royalist rising in Oporto, timed to coincide with this invasion, was brought prematurely to a head by Carbonario agents on Sept. 29, and this prevented the north from rising, except in the case of a few isolated villages.

King Manoel and the Pretender Dom Miguel met at Dover on Feb. 6 1912 to concert on common action, and the Royalist cause was strengthened by the great wealth of the Miguelists. On July 7 Couceiro again crossed the frontier, with a slightly larger force, but most of his arms and ammunition had been seized in Belgium and Galicia. The Royalist attacks on Valença and Chaves failed, and within a week they returned to Spain. Royalist risings in the northern provinces were speedily suppressed, and great excitement prevailed in the south, where the Carbonarios discovered a Royalist plot at Torres Vedras. D. João de Almeida and other prisoners-of-war were tried by court-martial and confined in the Lisbon Penitentiaria.

The Political Trials.—The arrests after the invasions of 1911 and 1912 were very numerous. Special tribunals were set up in Lisbon and Oporto in Jan. 1911 to try cases of political conspiracy, and in July 1912 Parliament voted still more stringent laws of defence. All persons suspected of reactionary opinions, religious or political, were in danger. Thousands of innocent persons were summarily arrested without the formulation of any definite charge and were confined for months in subterranean dungeons.

The chief instrument of this widespread system of espionage and terrorism was the organization of the Carbonarios. This

secret society, the *Jov. Port.* (Young Portugal), founded or revived by Senhor Arthur Duarte da Luze Almeida, forced through the Revolution of 1910 before the politicians were prepared for it. It assumed the functions of an unofficial police force and at times proved itself strong enough to attack the Republican Government and the army. Its members, who carried arms, were Republicans of the most extreme type; many had also joined its ranks in order to gratify some personal dislike or to secure the rewards given to successful informers. It was thus a body composed of dangerous fanatics. Completely blind to the political embarrassments which its actions might bring upon the Republic, it arrogated to itself the right of summary arrest. Senhor Chagas estimated that on Oct. 23 1911 there were 2,000 political prisoners awaiting trial, of whom 700 were innocent.

So notorious was the barbarity with which suspects were treated that a committee of prominent British residents was formed to investigate and, if possible, alleviate their condition. Several Portuguese Republican newspapers and prominent Conservative Republicans corroborated the findings of the British committee and diplomatic representations followed. But reforms were opposed by the Carbonarios and the Radical Republicans, and some of the worst outrages were committed under the weak Government which succeeded that of Senhor Chagas in Nov. 1911, with Dr. Augusto de Vasconcellos as premier, and under the third Coalition ministry formed by Dr. Duarte Leite in July 1912. One of the worst features was the intimidation of justice, the law courts being frequently filled with Carbonarios.

Hopes of improvement vanished when the Government resigned in Dec. 1912, and, after various attempts on the part of President Arriaga to form a moderate ministry, Dr. Afonso Costa, the Radical leader, came into power in Jan. 1913. In March of that year Adeline, Duchess of Bedford, with expert knowledge of prisons, visited the prisons of Lisbon, and meetings of protest against the treatment of the prisoners, held in London, advocated a general amnesty. Under the pressure of public opinion, the Minister of Justice in Jan. 1913 introduced a bill modifying the Penitentiaria régime, and in Feb. of that year 600 political prisoners and common criminals were excused from wearing the convict's hood, a pardon was granted to 300 prisoners, but the general amnesty was delayed till Feb. 1914.

The situation had become one of growing unrest and strikes were frequent. In April 1913 an attempted ultra-Radical *coup d'état*, in which a portion of the army and navy were implicated, was quelled and part of the crews of the "Vasco da Gama" and "S. Gabriel" were transported to Angra in the Azores. In June the Government decreed the suppression of the Lisbon Syndicalist Club. In July a movement similar to that of April was marked at Lisbon by attacks on the military barracks and was followed by numerous arrests. In Oct. 130 Republican prisoners were transferred to the fortress of Elvas, and a Monarchist movement at Lisbon and Oporto led to redoubled Carbonario activity. The amnesty bill became law on Feb. 22 1914 and in all about 1,300 prisoners (of whom over one-third had not been tried) and 1,500 exiles benefited by it, excluding Paiva Couceiro among others. The courts martial, which had been active during two years, were abolished by a decree of Aug. 19.

Dr. Afonso Costa, who gave much of his attention to finance, resigned on Feb. 9 1914, and Dr. Bernardino Machado became premier and was in office when the World War began.

On Dec. 13 1914 Dr. Machado was succeeded in the premiership by the Democrat, Senhor Victor Hugo de Azevedo Coutinho, President of the Chamber of Deputies, with a view to holding the elections which were fixed for March 7, but the Government's purpose was prevented by a military movement, and President Arriaga appealed to Gen. Pimenta de Castro to constitute a government representative of a wider body of opinion in the country; he formed a ministry on Jan. 28, 1915. The action of the new Government was conciliatory and had the support of the moderate Republicans led by Dr. Antonio José de Almeida; the country's foreign policy remained unchanged, but the activity of the Carbonarios was checked, the so-called Committee of Public Safety abolished and the refractory municipal councils dissolved.

The general election was now fixed for June 5 1915. In April an amnesty emptied the prisons. The Democrats were, however, able to count on the support of the marines and on May 14 the sailors mutinied, shot the captains of the "Almirante Reis" and "Vasco da Gama" and bombarded Lisbon, about 100 persons being killed. Pimenta de Castro resigned on May 15, and was arrested next day and transported to the Azores. The revolutionary committee nominated Senhor Chagas as premier, but on May 16 he was shot at and wounded in the train, on his way to Lisbon by Senator João de Freitas, who was killed. Chagas resigned on May 24 and was succeeded by Dr. José de Castro.

In a message addressed to Parliament Arriaga resigned the presidency as from May 29 (he died on March 5 1917); and after a short interim presidency under Dr. Theophilo Braga, he was definitely succeeded as President on Aug. 6 1915 by Dr. Bernardino Machado. The Government resigned in June, Castro again becoming premier, but he resigned in Nov. and Dr. Costa returned to office.

The Revolution of Dec. 1917.—On Dec. 5 1917 a revolution directed against the internal policy of Costa and the Democrats broke out at Lisbon. The rebels entrenched themselves in the Parque Eduardo VII. and their artillery opened fire upon the fleet. After two days' fighting, Gen. Norton de Mattos and Capt. Leotte do Rego took refuge on board a British ship in the Tagus. Dr. Costa and Dr. Soares were arrested; President Machado was placed under arrest, and on the 15th was conducted to the frontier. Vice-Adml. Machado dos Santos was released from prison and, with Maj. Sidonio Paes, the leader of the movement, and Capt. Feliciano Costa, formed a revolutionary committee. A provisional government was now constituted, Maj. Paes becoming President and Minister for War and Foreign Affairs. The Radical sailors mutinied on Jan. 8 1918 and bombarded Lisbon, but the movement was easily quelled, and several hundreds were deported to Africa. On Jan. 12 Paes left for the north, and at Oporto was received enthusiastically, as also on his return to Lisbon. A visit to the south in Feb. was equally successful.

In March 1918 Paes reconstructed his ministry, and the elections, on an enlarged franchise, were held throughout the country on April 28. The election of the President was held by universal suffrage on the same day. Paes was elected by over half a million votes and was proclaimed President on May 9. The Powers recognized the new régime, and on May 27 Great Britain raised her legation in Lisbon to the status of an embassy. The President opened Parliament in July. In Oct. a new Government was formed. Under a new system the President became also premier and ministers were called secretaries of state.

The first anniversary of the revolution was celebrated with national rejoicings on Dec. 5-8 1918. But on Dec. 14 President Paes was shot at the Rocio station by José Julio da Costa, and died a few minutes later. On Dec. 16 Adml. João de Canto e Castro was provisionally elected president, and in Jan. 1919 Senhor Tamagnini Barbosa formed a ministry, reviving the office of premier.

The Oporto Monarchy.—The Radical and Carbonario elements, which had hoped to benefit by President Paes' murder, rapidly became impatient, and a Democrat rising now broke out at Santarém, but the town was besieged by Government troops and the rebels surrendered. On Jan. 19 1919 the monarchy was proclaimed at Oporto, Braga and Viseu, Capt. Paiva Couceiro becoming regent and acting also as premier and minister of finance. At Lisbon the Royalists occupied Fort Monsanto and bombarded the city, but they were overcome without difficulty by the marines and Carbonarios. A considerable Republican army was sent against Oporto, but, though part of the regular troops drafted from Lisbon deserted, the Royalist forces were weak and did not reach Aveiro. The fighting during the three weeks of civil war was not of a serious character. A counter-revolutionary movement at Oporto in Feb. led to the restoration of the Republic, and the main result of these ill-timed risings was to fill the prisons and bring the Radicals into power. At Lisbon the marines and Carbonarios, in Feb., demanded government by "soviets" and the abolition of the official police. Severe street

fighting and serious outrages occurred, including the burning down of a block of government offices in Black-Horse Square and of the Limoeiro prison. This had the effect of forcing the new authorities to copy the disciplinary methods of President Paes.

Government by Groups.—Senhor José Relvas became premier on Jan. 27 1919, and was succeeded in March by the Democrat, Dr. Domingo Pereira. It now became possible to hold the elections, and in May a Radical majority was returned. On June 1 Adml. Canto e Castro announced his intention of resigning the presidency, the candidate of the Democratic party, Dr. Antonio José de Almeida, being subsequently elected President on Aug. 6. On June 28 the Democratic Col. Sa Cardoso constituted a more stable ministry, which lasted till Jan. 7 1920. There followed a succession of short-lived ministries, under Senhor Fernandez Costa, Dr. Domingo Pereira, Col. Antonio Maria Baptista, Dr. Ramos Preto, Senhor Antonio Maria da Silva, Senhor Antonio Granjo (July to Nov. 15), Dr. Alvaro de Castro, and Lt.-Col. Liberato Pinto (Nov. 29 to Feb. 1921); and on March 2 1921 a new Coalition ministry (composed of Democrats, Reconstituents, Dissidents and members of the Popular party, all offshoots of the original Republican Democrat party) was formed, under the premiership of Dr. Bernardino Machado. A military pronouncement on May 20 caused the resignation of Dr. Machado. He was succeeded by a Liberal ministry under Dr. Barros Queiroz, who dissolved Parliament and held a general election on July 10.

The absence of a firm guiding hand had been especially felt after the murder of President Paes, and successive governments seemed to lose control over the finances. No government was strong enough to raise an internal loan, to revise the system of taxation or levy a war-profits tax, and, while the taxes were paid in worthless paper money, the Government had to buy wheat and pay the service on the debt in gold. Social unrest was chronic in March 1920; there was a general strike of civil, and post and telegraph, servants; a railway strike which began on Oct. 1 1920, lasted 70 days; and a newspaper strike in 1921 for over two months. The Royalists showed themselves willing to exchange revolutionary for constitutional opposition, and King Manoel had constantly deprecated any revolutionary movement in view of the grave crisis through which the country was passing. The death of his uncle, the Duke of Oporto in 1920, left King Manoel without an heir to the throne. D. Miguel, Duke of Viseu, and his father D. Miguel, Duke of Braganza, renounced their right to the throne of Portugal in favour of D. Duarte Nuno, the younger son of the latter, born Sept. 23 1907.

The World War.—At a special joint sitting of both Chambers on Aug. 7 1914 Portugal proclaimed her loyalty to the British Alliance, and on Nov. 23 formally committed herself to participation in military operations. She served the cause of the Allies effectively by furnishing munitions, guns, and a division of artillery, and acted in close coöperation with Great Britain. In Oct. a Portuguese military mission arrived in London and a commercial mission followed in November. On Sept. 11 the first expedition of Portuguese troops left for Africa under the command of Colonel Alves Rôçadas and Massano de Amorim, and fresh contingents followed at intervals, 40,000 troops in all being despatched for the defence of the colonies. Germany had not waited to be at war with Portugal in order to attack them. As early as Aug. 24 1914 a raid was made on the Portuguese post of Muziwa on the northern frontier of Mozambique. On Oct. 19 the Germans attacked Naulila (on the Angola frontier), where more serious fighting occurred two months later, and on Oct. 30 they stormed the fortress of Kwangar and put the garrison to the sword. On April 11 1916 Portuguese troops occupied Kionga (S. of the Rovuma River), which Germany had seized in 1894, and on May 27 they crossed the Rovuma River. They were still coöperating with the British in rounding up the Germans when war ended.

The British Government had deprecated any unnecessary intervention of Portugal in the war, but agreed to the requisitioning of German ships lying in Portuguese ports, and this was carried into effect in Feb. 1916. Consequently, Germany retaliated by declaring war on Portugal on March 9, and the declaration of

war between Portugal and Austria followed on March 16. The Government resigned in order to make way for a national ministry, constituted on March 15 under Dr. Almeida. Capt. Leotte do Rego was appointed commander-in-chief of the naval division. French and British military missions arrived in Lisbon in March, and a British naval mission arrived in April. In June a first division of 20,000 men was concentrated at Tancos, where training began. Of the Germans in Portugal many had already left and 400 were interned. German submarines were active off the coast of Portugal during the autumn, many ships being sunk in 1917; Ponta Delgada was attacked by one on July 4 1917, and attacks were also made on Funchal and Cabo Verde in December.

On the declaration of war in March 1916 the few Royalist journals still permitted to appear in Portugal made patriotic declarations, and a message from King Manoel in Nov. exhorted his followers to set country above party. In Dec. a revolutionary movement was suppressed at Thomar and its leader, Machado dos Santos, imprisoned. In April 1917 Dr. Costa formed a new ministry. By a decree of Jan. 17 1917 Gen. Fernando Tamagnini de Alorn was given command of the Portuguese Expeditionary Force, and by July there were over 40,000 Portuguese troops on the western front, with 20,000 in Portugal ready to reinforce them. On April 9 1918, on the river Lys, the Portuguese contingent were subjected to a formidable attack by the Germans, and they were compelled to fall back, leaving a large number of prisoners. Subsequently Portuguese troops took part in the victorious entry into Lille.

Dr. Egas Moniz (later replaced by Dr. Afonso Costa) was appointed to represent Portugal at the Peace Conference, and in Jan. 1919, at the instance of Great Britain, the number of delegates to the Conference was increased to two. Portugal came out of the war with a crushing debt, but her colonies were assured to her, and her economic future was promising. The Peace Treaty was ratified on March 30 1920. At the Spa Conference in July 1920 Portugal secured 0.75% as her share of the indemnity from Germany, and also received Kionga.

Legislation.—One of the first decrees of the provisional government (Oct. 29 1910) ordained that press offences should be tried before a jury, but the liberty of the press under the Republic was more nominal than real and no Royalist or clerical newspaper was left long unmolested. The law of divorce (Nov. 4 1910) allowed, among other grounds for divorce, insanity, a long term of imprisonment, desertion, inveterate gambling and mutual consent. Gambling, at first legalized, was totally prohibited in 1919. Duelling was forbidden in Jan. 1911. On May 30 1911 Greenwich time was officially adopted, all clocks being advanced 37 minutes at midnight on Dec. 31 1911. In Sept. 1911 the Marconi system of wireless telegraphy was adopted. On June 14 1913 Portugal and Great Britain signed an agreement regulating the opium monopoly in Macao and Hong-Kong. On Aug. 15 1914 administrative and financial autonomy was given to the colonies. The employment of native labour in the Portuguese colonies was regulated by a very elaborate decree of Oct. 14 1914, modifying and developing the law of May 27 1911 and the decree of Oct. 1 1913.

Legislation on the subject of education was voluminous, but comparatively little was achieved to replace the schools of the expelled religious orders. By the decree of March 29 1911 primary education became neutral, laic and compulsory. Each parish was to have at least one boys' and one girls' school, the cost to be shared between the State and the town councils. In the two following years 991 new schools were decreed, but in March 1913 536 were still non-existent. The sum of £40,000 destined in 1913 for the building of primary schools, was apportioned among 180 schools. By a decree of Sept. 11 1913, in order to encourage industrial education and relieve the lycées of Lisbon, Oporto and Coimbra, the number of students admissible to these latter was limited to a total of 4,850. Secondary education was remodelled by decrees of July 14 and Sept. 8 1918. In May 1914 a military school of aeronautics was created. Other decrees dealt with agricultural credit (1914), accidents to workmen (1913 and 1914) and work of minors and women (1915). On March 9 1918 a Ministry of Agriculture was created, but the decrees stimulating production were of a tentative and contradictory character. Uncultivated land has to pay a small tax per acre and becomes the property of the State if still uncultivated in 20 years from 1911. In March 1921 a much-needed bill was introduced providing for the building of new roads and for the repair each year of 312 miles of existing roads during 1922-31.

Defence.—On Jan. 19 1911 a commission appointed to reorganize the navy recommended the acquisition from Great Britain of three battleships of the dreadnought type, similar to the "Minas Geraes" of the Brazilian navy. This recommendation was adopted in the new

naval programme submitted by the Minister of Marine in Dec. 1911, which involved the purchase of 3 battleships of 20,000 tons each, 3 scouts of 3,000 tons, 12 torpedo-boats of 820 tons and 6 submarines. On May 1 1912 a bill was introduced fixing the naval force at 4,500 men, as compared with 5,687 in 1910. On Jan. 27 1913 a commission was appointed for the creation of a naval arsenal on the S. bank of the Tagus.

Finance.—The average annual revenue from 1907-8 till the revolution (1910) was £14,456,000, and the average deficit £500,000. After the revolution special attention was given to finance. A committee appointed to examine into various loans made by the State to the House of Braganza assessed the total to June 18 1912 at nearly £800,000, of which £720,000 had been advanced to King Carlos, £24,500 to the Duke of Oporto and £16,400 to Queen Amelia. The Government decided to reimburse itself from King Manoel's property in Portugal.

The budget for 1911-2 showed a deficit reduced to £435,000, but an increased expenditure of £1,026,800. The deficit for 1912-3, estimated at £710,000, was converted into a surplus of £33,400 in August. The 1913-4 budget showed a total revenue of £15,178,843 and a surplus of £195,778, of which £111,800 was destined for the new naval programme. These figures were obtained by adding to the debt. On Aug. 31 1913 the debt stood at £145,917,500, an increase of £1,596,000 over its amount on Dec. 31 1912. In presenting the 1915-6 budget, with an estimated deficit of £2,120,400, it was decided to separate ordinary and war expenditure, but in practice, although two budgets were presented, the expenditure was not kept strictly separate. The double budget of 1916-7 provided for an ordinary expenditure of £17,220,000, with £403,400 deficit, and a war expenditure of £15,000,000. The war added an average of £20,000,000 yearly to the debt, which reached £227,000,000 on July 1 1918. Portugal was further indebted to Great Britain to the extent of £16,000,000 advanced for expenses at the front and £2,000,000 for war expenses in Portugal. The 1920-1 budget, presented in Feb. 1920, before that of the previous year had been voted, showed a revenue of £26,581,000 and a deficit of £25,555,000, an increase of £7,333,000 over the deficit of the previous year. It was proposed to extinguish the deficit by a reduction in the cost of the civil service and a war-profits tax, calculated to yield £22,222,000, but the Government fell before the proposals could be carried into effect. In Dec. 1920 heavy property and industrial taxes were imposed. By the 1921-2 estimates, presented in Jan. 1921, the deficit was increased to £58,888,000 on a total expenditure of £106,610,000. At the end of 1920 the debt was unofficially estimated as follows: external £53,777,000, floating £123,939,000, internal £325,333,000—total £503,049,000. The paper currency, which at the end of 1910 stood at £16,000,000 (at par of exchange, namely, 4,500 reis = £1), had risen to £82,361,000 in Dec. 1919, and to £118,361,000 in Sept. 1920. A further increase of £44,444,000 was voted by Parliament in Dec. 1920. In that month the 3% external debt was quoted at 22. Theagio on gold, which was 5 in Oct. 1910 and 16 in Aug. 1914, exceeded 1,100% in Feb. 1921, but fell to half that amount a few months later. The floating debt, which immediately before the war was £19,555,000 (at par of exchange), stood at £119,555,000 on Dec. 31 1919. The heavy depreciation in the exchange, however, must be allowed for.

In Feb. 1921 the Banco Nacional Ultramarino became the sole agent of the Royal Bank of Scotland and of some English banks.

Commerce.—Portugal's foreign trade, which in 1913 had reached £22,094,500 in imports and £11,355,000 in exports, further expanded during the World War, and in 1917 amounted (at par of exchange) to £37,391,700 imports and £19,121,500 exports. The trade between Portugal and her African colonies almost doubled between 1911 and 1917. In 1917 5,860 ships of 4,906,599 tonnage entered Portuguese ports, as compared with 10,638 of 24,368,120 tonnage in 1913. The total tonnage of German ships seized in 1916 was 242,441, of which 157,333 were handed over to the Allies. Portugal lost 28,637 tons of shipping by enemy action, and her merchant shipping at the end of 1918 stood at 100,000 tons.

A treaty of arbitration for five years, between Portugal and Great Britain, was signed at London on Nov. 16 1914. The commercial treaty between the two countries, signed at Lisbon on Aug. 12 1914, became effective on Sept. 23 1916.

Foreign Exchange.—After the war serious efforts were made to grapple with the problem of the exchange, which was aggravated by the decree of May 31 1919 placing the financial agency at Rio de Janeiro in private hands. A decree of April 27 1918 provided that when the exchange was at 29½, 50% of the customs duties should be paid in gold at that rate and 50% at par, until the exchange reached 38½, when the whole of the duties was to be paid in gold at par. A decree of Feb. 4 1920 totally prohibited a large number of imports, thus depriving the exchequer of an important source of revenue. Neither the Banking Consortium (Jan. 10-May 26 1920) nor the attempt to fix the rate of exchange officially, was effective in preventing a further rapid depreciation in Portuguese money, owing to the almost complete absence of gold (the reserve having fallen to under 2% in 1920) and to decreased production. As a result of the cost of labour and the fixed price of bread, cultivation of wheat diminished steadily from 1918, its best year. In 1918 the 248 million kgm. produced fell short of requirements by 96 million kilograms. The most important export trade—wine—suffered during the war from trans-

port difficulties and, later, from the reduced demand in Great Britain and the loss of the markets of the United States, Canada, Russia and Norway. The wine trade attained its maximum in 1919, when the cost of transport fell from £15 to £4 a pipe and Great Britain imported 12,458,220 gallons. In 1920 Great Britain imported only 5,914,575 gal. and a huge stock was left on the hands of the merchants. Portuguese manufacturing industries, which expanded considerably during the war, despite the coal shortage, were similarly affected by decreased demand in 1920, for which the expansion of colonial trade did not entirely compensate.

Population.—The pop. of Portugal numbered 5,547,708 in 1911, not including the inhabitants of the Azores and Madeira, which amounted to 412,348 in the same year. The pop. of the chief towns (1911 census) were: Lisbon 435,399, Oporto 194,099, Setúbal 30,346, Ilhavo 14,130, Póvoa de Varzim 12,115, Tavira 11,665, Faro 12,680, Ovar 11,416, Olhão 10,890, Viana do Castelo 10,486, Aveiro 11,523, Loulé 19,688, Coimbra 20,581, Évora 17,901, Covilhã 15,745, Elvas 10,645, Portalegre 11,503, Palmella 13,318, Torres Novas 13,961.

Literature.—Literature in Portugal from 1911 to 1921 was marked chiefly by the death of prominent men of letters—of philologists, Gonçalves Viana (1914), Epiphânio Dias (1916), Júlio Moreira (1917) and Adolpho Coelho (1919); critics, Ramalho Ortigão (1917) and D. Maria Amália Vaz de Carvalho (1921); novelists, Fialho de Almeida (1911), Abel Botelho (1917) and Teixeira de Queiroz (1919); the dramatist Marcelino Mesquita (1919); poets, António Feijó (1917), João Penha (1919) and Gomes Leal (1921). But although the revolution was followed by no great literary revival, most useful work was accomplished, including much-needed and important reprints and editions of the classics. Among these may be mentioned the scholarly editions of Dr. J. J. Nunes and of Dr. Esteves Pereira, who in 1918 published the *Livro da Monarquia* of King João I. from the original manuscript. Valuable material for the future historian of Portugal was brought together by the researches of several scholars, among whom Mr. Edgar Prestage specialized on the 17th century. The *Revista de História* has been published regularly since 1912. Senhor J. Lucio de Azevedo followed up his *Life of Pombal* with notable studies on Antonio Vieira. Dr. Leite de Vasconcellos' invaluable *Revista Lusitania* reached its 20th volume in 1917. In poetry a national tendency set in which is strongly marked in Dr. Lopes Vieira's *Ilhas de Bruma* (1917). The veteran poet, Senhor Guerra Junqueiro, published *Poesias Dispersas* in 1920. In the field of essay the glowing style and national fervour of Senhor Antero de Figueiredo in *Leonor Teles* (1916), *Jornadas em Portugal* (1918), *Recordações e Viagens* (2nd ed. 1916), and other works, are notable. The growing interest in Portuguese literature in England was marked by the foundation of a chair of Portuguese literature at King's College, London, in 1917.

Herculanio, *História de Portugal*, illustrated edition in 8 vols. (1914-6); H. da Gama Barros, *História da Administração pública em Portugal nos séculos XII, e XV.* (3 vols. 1895-6 and 1914); Dr. Mendes dos Remedios, *História da Literatura Portuguesa* (5th ed. 1921); F. de Figueiredo, *História da Literatura Romântica Portuguesa* (1913), *História da Literatura Realista* (1914), *História da Literatura Clássica* (1917), dealing with the 16th century, and *A Crítica Literária como Ciência* (3rd ed. 1920). What purports to be a summary of the literature of Dr. Theophilo Braga consists of 4 vols.: *Época Média* (1909), *Renascença* (1914), *Os Seiscentistas* (1916), *Os Arcades* (1918).

PORTUGUESE EAST AFRICA, or MOZAMBIQUE (see 22.163).—As the result of the World War in what was formerly the German territory adjoining, Portuguese East Africa has become bordered landward entirely by British, or British administered, territory. In 1919 "the Kionga triangle," some 400 sq. m. in size, and including the southern shore of the estuary of the Rovuma, was transferred to the province—having been part of German East Africa. The pop. in 1918 was roughly estimated at 3,000,000 to 3,500,000; no systematic census had been made and the inhabitants in areas not controlled by the Portuguese were not included. Europeans, exclusive of troops, numbered some 22,000; Asiatics (mainly Indian traders) 15,000-18,000. Lourenço Marques, the capital, with suburbs had about 20,000 inhabitants of whom 5,500 were white (700 being British).

Products and Trade.—An increase in the area under sugar, greater attention to the plantations of coco-nut palms (for copra), the introduction of sisal growing (from German East Africa) and the cultivation of maize for export were directions in which endeavours

were made to increase the resources of the province in 1917-21. The sugar plantations were mainly in the region between Beira and the Zambezi, a region governed under charter by the Company of Mozambique, in which British capital was largely interested. Between 1911 and 1919 the area under sugar trebled and the output reached 35,000 tons yearly. Most of it was produced by the Sena Sugar Co. and shipped at Beira. Sisal was cultivated mostly in the Quilimane area; in 1916 the export was 2,200 tons of fibre.

Before the World War trade was mainly divided between British, Portuguese and Germans; the Germans financed the Banyans (Indian traders) who retailed "Kafir truck" to the natives, a business worth £250,000 or more a year. In return the natives sold, principally, ground nuts of which some 2,000 tons were exported annually. North of the Zambezi German merchants had nearly all the trade, both import and export, and had begun to oust even the Banyan. In the S., at Delagoa Bay and Beira British firms held over 50% of the trade. The war eliminated the German trader.

No uniform system of trade statistics was adopted in the three administrative areas into which the province was divided. The following figures are approximations to accuracy:—in 1911 imports £8,250,000, exports £2,250,000. The imports include some £6,800,000, in and out transit trade through Delagoa Bay and Beira. For 1913 the imports (excluding transit trade) were given at £2,053,000; exports at £2,720,000. Portuguese figures for 1917 (excluding Beira) gave the imports at £2,800,000; the exports at £1,500,000, not reckoning transit trade or reexports.

The imports for local use were mainly textiles, provisions and machinery. Large quantities of wine, "vinho colonial," are imported from Portugal for native consumption—in 1913 the amount received at Lourenço Marques alone was 1,620,000 gallons valued at £105,000. In 1920 alcohol was declared by the high commissioner of Mozambique to be the curse of the province. The great bulk of the trade was in transit to or from the Transvaal, Rhodesia or British Nyasaland. The import of most direct benefit to the province was coal from the Transvaal. From 1912 onward Lourenço Marques became important both for the export and bunkering trade. (For the relations of the province with the Transvaal see DELAGOA BAY.)

Communications.—During 1910-20 several short lines of railway were built from the seaports. The largest scheme was to connect Delagoa Bay and Inhambane. This line with a total length of 280 m. was planned in independent sections, and 160 m. had been completed by 1916; the central section had not been built in 1920. The building of a railway (about 170 m. long) from Beira to the Zambezi, opposite Chindio, was begun in 1920 under a guarantee of the British Nyasaland Protectorate, its object being to afford that protectorate an ocean gateway. From Chindio a railway, completed in May 1915, goes to Port Herald where it connects with the Shire Highlands railway. A route for a railway from Port Amelia to Lake Nyasa was surveyed in 1912. The line would have been built by a German company but for the outbreak of the World War. Up to 1921 a few miles only of rails had been laid from Port Amelia. Wireless telegraph stations have been erected at Delagoa Bay, Inhambane and Mozambique town.

Finance.—Revenue was obtained chiefly from a hut tax, customs and taxes on emigration, i.e. a poll tax paid to the provincial authorities for natives recruited for the Transvaal gold mines and other work. In 1913-4 revenue and expenditure were budgeted for £1,312,000; in 1917-8 at £1,809,000. "Cost of administration" was given as the chief item of expenditure, not unreasonably, as in 1917 there were over 10,000 persons in Government pay.

History.—The efforts made by chartered companies and reforming governors to develop the province left its vast natural resources up to 1920 scarcely touched. The Portuguese lacked capital with which to undertake large operations, the settler class was not on the whole of a satisfactory character, the administrative system was very defective, and up to 1914 the interests of the province were entirely subordinated to the assumed interests of Portugal. In that year following an agitation in which the then governor-general of the province, Senhor de Magalhães, took the lead, Mozambique was granted partial autonomy and in 1920, when Dr. Brito Camacho was appointed high commissioner, further reforms were enacted. The general trend of events during 1910-20 was to show the province as of value chiefly as a passage-way to and from the Transvaal, Rhodesia and British Nyasaland. Partly because of the necessity of keeping this passage-way open it was in this period that Portuguese authority was first made fairly effective throughout the province. Moslem chiefs along the coast in the region opposite Mozambique Island were subjugated by 1910, after a four years' contest, and the hinterland tribes then submitted with little resistance. The occupation of the interior of Portuguese Nyasaland, begun in earnest in 1909, met, however, with strong opposition from the natives and was not completed till 1912, when Mataka, the most powerful opponent of the

war between Portugal and Austria followed on March 16. The Government resigned in order to make way for a national ministry, constituted on March 15 under Dr. Almeida. Capt. Leotte do Rego was appointed commander-in-chief of the naval division. French and British military missions arrived in Lisbon in March, and a British naval mission arrived in April. In June a first division of 20,000 men was concentrated at Tancos, where training began. Of the Germans in Portugal many had already left and 400 were interned. German submarines were active off the coast of Portugal during the autumn, many ships being sunk in 1917; Ponta Delgada was attacked by one on July 4 1917, and attacks were also made on Funchal and Cabo Verde in December.

On the declaration of war in March 1916 the few Royalist journals still permitted to appear in Portugal made patriotic declarations, and a message from King Manoel in Nov. exhorted his followers to set country above party. In Dec. a revolutionary movement was suppressed at Thomar and its leader, Machado dos Santos, imprisoned. In April 1917 Dr. Costa formed a new ministry. By a decree of Jan. 17 1917 Gen. Fernando Tamagnini de Alorn was given command of the Portuguese Expeditionary Force, and by July there were over 40,000 Portuguese troops on the western front, with 20,000 in Portugal ready to reinforce them. On April 9 1918, on the river Lys, the Portuguese contingent were subjected to a formidable attack by the Germans, and they were compelled to fall back, leaving a large number of prisoners. Subsequently Portuguese troops took part in the victorious entry into Lille.

Dr. Egas Moniz (later replaced by Dr. Afonso Costa) was appointed to represent Portugal at the Peace Conference, and in Jan. 1919, at the instance of Great Britain, the number of delegates to the Conference was increased to two. Portugal came out of the war with a crushing debt, but her colonies were assured to her, and her economic future was promising. The Peace Treaty was ratified on March 30 1920. At the Spa Conference in July 1920 Portugal secured 0.75% as her share of the indemnity from Germany, and also received Kionga.

Legislation.—One of the first decrees of the provisional government (Oct. 29 1910) ordained that press offences should be tried before a jury, but the liberty of the press under the Republic was more nominal than real and no Royalist or clerical newspaper was left long unmolested. The law of divorce (Nov. 4 1910) allowed, among other grounds for divorce, insanity, a long term of imprisonment, desertion, inveterate gambling and mutual consent. Gambling, at first legalized, was totally prohibited in 1919. Duelling was forbidden in Jan. 1911. On May 30 1911 Greenwich time was officially adopted, all clocks being advanced 37 minutes at midnight on Dec. 31 1911. In Sept. 1911 the Marconi system of wireless telegraphy was adopted. On June 14 1913 Portugal and Great Britain signed an agreement regulating the opium monopoly in Macao and Hong-Kong. On Aug. 15 1914 administrative and financial autonomy was given to the colonies. The employment of native labour in the Portuguese colonies was regulated by a very elaborate decree of Oct. 14 1914, modifying and developing the law of May 27 1911 and the decree of Oct. 1 1913.

Legislation on the subject of education was voluminous, but comparatively little was achieved to replace the schools of the expelled religious orders. By the decree of March 29 1911 primary education became neutral, laic and compulsory. Each parish was to have at least one boys' and one girls' school, the cost to be shared between the State and the town councils. In the two following years 991 new schools were decreed, but in March 1913 536 were still non-existent. The sum of £40,000 destined in 1913 for the building of primary schools, was apportioned among 180 schools. By a decree of Sept. 11 1913, in order to encourage industrial education and relieve the lycées of Lisbon, Oporto and Coimbra, the number of students admissible to these latter was limited to a total of 4,850. Secondary education was remodelled by decrees of July 14 and Sept. 8 1918. In May 1914 a military school of aeronautics was created. Other decrees dealt with agricultural credit (1914), accidents to workmen (1913 and 1914) and work of minors and women (1915). On March 9 1918 a Ministry of Agriculture was created, but the decrees stimulating production were of a tentative and contradictory character. Uncultivated land has to pay a small tax per acre and becomes the property of the State if still uncultivated in 20 years from 1911. In March 1921 a much-needed bill was introduced providing for the building of new roads and for the repair each year of 312 miles of existing roads during 1922-31.

Defence.—On Jan. 19 1911 a commission appointed to reorganize the navy recommended the acquisition from Great Britain of three battleships of the dreadnought type, similar to the "Minas Geraes" of the Brazilian navy. This recommendation was adopted in the new

naval programme submitted by the Minister of Marine in Dec. 1911, which involved the purchase of 3 battleships of 20,000 tons each, 3 scouts of 3,000 tons, 12 torpedo-boats of 820 tons and 6 submarines. On May 1 1912 a bill was introduced fixing the naval force at 4,500 men, as compared with 5,687 in 1910. On Jan. 27 1913 a commission was appointed for the creation of a naval arsenal on the S. bank of the Tagus.

Finance.—The average annual revenue from 1907-8 till the revolution (1910) was £14,456,000, and the average deficit £500,000. After the revolution special attention was given to finance. A committee appointed to examine into various loans made by the State to the House of Braganza assessed the total to June 18 1912 at nearly £800,000, of which £720,000 had been advanced to King Carlos, £24,500 to the Duke of Oporto and £16,400 to Queen Amelia. The Government decided to reimburse itself from King Manoel's property in Portugal.

The budget for 1911-2 showed a deficit reduced to £435,000, but an increased expenditure of £1,026,800. The deficit for 1912-3, estimated at £710,000, was converted into a surplus of £33,400 in August. The 1913-4 budget showed a total revenue of £15,178,843 and a surplus of £195,778, of which £111,800 was destined for the new naval programme. These figures were obtained by adding to the debt. On Aug. 31 1913 the debt stood at £145,917,500, an increase of £1,596,000 over its amount on Dec. 31 1912. In presenting the 1915-6 budget, with an estimated deficit of £2,120,400, it was decided to separate ordinary and war expenditure, but in practice, although two budgets were presented, the expenditure was not kept strictly separate. The double budget of 1916-7 provided for an ordinary expenditure of £17,220,000, with £403,400 deficit, and a war expenditure of £15,000,000. The war added an average of £20,000,000 yearly to the debt, which reached £227,000,000 on July 1 1918. Portugal was further indebted to Great Britain to the extent of £16,000,000 advanced for expenses at the front and £2,000,000 for war expenses in Portugal. The 1920-1 budget, presented in Feb. 1920, before that of the previous year had been voted, showed a revenue of £26,581,000 and a deficit of £25,555,000, an increase of £7,333,000 over the deficit of the previous year. It was proposed to extinguish the deficit by a reduction in the cost of the civil service and a war-profits tax, calculated to yield £22,222,000, but the Government fell before the proposals could be carried into effect. In Dec. 1920 heavy property and industrial taxes were imposed. By the 1921-2 estimates, presented in Jan. 1921, the deficit was increased to £58,888,000 on a total expenditure of £106,610,000. At the end of 1920 the debt was unofficially estimated as follows: external £53,777,000, floating £123,939,000, internal £325,333,000—total £503,049,000. The paper currency, which at the end of 1910 stood at £16,000,000 (at par of exchange, namely, 4,500 reis = £1), had risen to £82,361,000 in Dec. 1919, and to £118,361,000 in Sept. 1920. A further increase of £44,444,000 was voted by Parliament in Dec. 1920. In that month the 3% external debt was quoted at 22. Theagio on gold, which was 5 in Oct. 1910 and 16 in Aug. 1914, exceeded 1,100% in Feb. 1921, but fell to half that amount a few months later. The floating debt, which immediately before the war was £19,555,000 (at par of exchange), stood at £119,555,000 on Dec. 31 1919. The heavy depreciation in the exchange, however, must be allowed for.

In Feb. 1921 the Banco Nacional Ultramarino became the sole agent of the Royal Bank of Scotland and of some English banks.

Commerce.—Portugal's foreign trade, which in 1913 had reached £22,094,500 in imports and £11,355,000 in exports, further expanded during the World War, and in 1917 amounted (at par of exchange) to £37,391,700 imports and £19,121,500 exports. The trade between Portugal and her African colonies almost doubled between 1911 and 1917. In 1917 5,860 ships of 4,906,599 tonnage entered Portuguese ports, as compared with 10,638 of 24,368,120 tonnage in 1913. The total tonnage of German ships seized in 1916 was 242,441, of which 157,333 were handed over to the Allies. Portugal lost 28,637 tons of shipping by enemy action, and her merchant shipping at the end of 1918 stood at 100,000 tons.

A treaty of arbitration for five years, between Portugal and Great Britain, was signed at London on Nov. 16 1914. The commercial treaty between the two countries, signed at Lisbon on Aug. 12 1914, became effective on Sept. 23 1916.

Foreign Exchange.—After the war serious efforts were made to grapple with the problem of the exchange, which was aggravated by the decree of May 31 1919 placing the financial agency at Rio de Janeiro in private hands. A decree of April 27 1918 provided that when the exchange was at 29½, 50% of the customs duties should be paid in gold at that rate and 50% at par, until the exchange reached 38½, when the whole of the duties was to be paid in gold at par. A decree of Feb. 4 1920 totally prohibited a large number of imports, thus depriving the exchequer of an important source of revenue. Neither the Banking Consortium (Jan. 10-May 26 1920) nor the attempt to fix the rate of exchange officially, was effective in preventing a further rapid depreciation in Portuguese money, owing to the almost complete absence of gold (the reserve having fallen to under 2% in 1920) and to decreased production. As a result of the cost of labour and the fixed price of bread, cultivation of wheat diminished steadily from 1918, its best year. In 1918 the 248 million kgm. produced fell short of requirements by 96 million kilograms. The most important export trade—wine—suffered during the war from trans-

POULTRY

335

It is interesting in comparison to note that, according to an answer given by Sir R. Sanders for the Minister of Agriculture in the House of Commons on Feb. 24 1921, the estimated value of the total wheat crop of the United Kingdom in 1920 was £31,000,000. Also in a recent Report on the Trade in Imports and Exports at the Irish ports it was stated that the value of the Irish eggs, poultry and feathers exported was in one year greater by about £13,000,000 than the store cattle trade and nearly equal in value to the export in fat cattle.

There is a further important aspect of the effect of the demand for table eggs and poultry in the United Kingdom in the national finances, viz. the large sums paid annually to foreign countries for supplies to supplement the insufficient home production. Tables 1 and 2 show the annual quantities and values of these imports for the years 1913, 1919 and 1920:—

the increasing appreciation shown by poultry-keepers of the commercial importance of high egg yield, and the consequent demand for stock, specially selected and bred for this quality. A great stimulus was given to this development by the introduction of public *laying competitions*, the object of which was to test the egg-producing capacities of various breeders' birds and also to gain information regarding the relative fecundity of existing strains and breeds. The introduction of these laying competitions in England was due to the enterprise shown by the Northern Utility Poultry Society of Burley, Lancashire, and the Utility Poultry Club (now the National Utility Poultry Society), and at first

TABLE 2.—Comparative Imports of Poultry in Cwt.

From	1913 Cwt.	1919 Cwt.	1920 Cwt.
Russia	119,944	8	66
France	31,175	3,083	27,112
Austria-Hungary	26,674	Nil	1,396
U. S. A.	54,242	100,859	9,872
Other Countries	46,430	43,617	56,018
Total quantities	278,465	147,567	94,464
Total values	£954,540	£1,527,992	£817,872

The figures in Tables 1 and 2 show that in 1920, as compared with 1913, the total value of imported eggs and poultry had increased from £10,545,142 to £12,396,968, whilst the total quantity had decreased in the case of eggs from 21,579,950 great hundreds to 7,070,266 great hundreds; and in the case of dead poultry from 278,465 cwt. to 94,464 cwt. Thus, reckoning that the eggs averaged 14 lb. per 120, the imports in 1920 were less by 90,685 tons than in 1913, whilst the imports of dead poultry were less by 9,200 tons. It appears, therefore, that the total annual value of the eggs and poultry consumed in the United Kingdom had in 1920 reached the following approximate huge sum:—

British production	£37,000,000
Irish	22,352,578
Imported	12,396,968
Total	£71,749,546

From the foregoing it would seem that the opportunities for increasing the production of eggs and poultry in the United Kingdom were in 1921 greater than ever. Russia, the largest supplier in pre-war days, had practically ceased her exports, whilst Italy and the countries formerly included in Austria-Hungary would probably take some years to recover their former exporting capabilities. Much must depend, however, upon the capacity of the British people to adopt efficient methods of cheaper production. There is little doubt that the majority of British consumers would prefer to eat fresh British eggs and poultry rather than those of foreign origin, preserved or otherwise, provided the price of the home article is not too high. It is largely a matter of cost of production and methods of marketing.

One of the most interesting developments in poultry-keeping of recent years has been the growth of stock poultry farms whose main object is the production of pure-bred poultry of heavy laying capacity. This development was no doubt primarily due to

competitions were conducted over four winter months, commencing in October. Thus the productive capacity of the birds was tested at the time of the year when eggs are most difficult to obtain, and competing breeders were compelled to hatch their birds early if they wished them to obtain a good place in the trials.

The introduction of these competitions marks an important epoch in the history of the poultry industry, as attention was thereby focussed upon the great variation in fecundity of various strains and breeds, whilst the commercial importance of high egg yield was forcibly demonstrated. For the first few years trap-nests were not used, records of the egg yield of each pen of four birds being taken. In 1902, however, trap-nests were introduced and the individual records were taken. In 1912-13 the competitions were extended to twelve-month periods, and a grant in aid of this work was given to the Utility Poultry Society in conjunction with the Harper Adams Agricultural College, Newport, Salop, by the Board of Agriculture and Fisheries. It was no doubt realized by the Board that the educational value of these competitions was very great. Not only was information obtained regarding the relative productivity of different birds, "strains," and breeds, but also regarding size and colour of egg, comparative seasonal production, period of brooding, cost of food per bird and net cost of egg production, value of different systems of housing, feeding, and general management. In fact it is open to question if the full educational value of laying competitions or trials had in 1921 been fully exploited.

The National Utility Society continued to organize trials annually, and after 1916-17 these were carried out for the Society by the Great Eastern Railway Co. at Bentley, Ipswich. This Company in conjunction with the Utility Duck Club also arranged in 1921 a laying trial for ducks. The trap-nesting arrangement for these birds is very ingenious as the ducks are enticed into the nests by regularly placing the food in small pens in front of the nests, but inside the

traps. Only one duck can obtain admission to each pen or nest, and as the birds are plainly marked with distinctive rings very little handling is necessary.

Several other public laying trials were being conducted in 1921 in various parts of the United Kingdom: at Burnley, Lancashire, by the Northern Poultry Society; at Newport, Salop, by the Harper Adams Agricultural College; at Wye, Kent, by the South Eastern Agricultural College; at Birmingham by the Midland Fur and

at too high a cost in other directions and that high resistance to disease, low chicken mortality, and reasonably sized eggs are also matters of considerable importance.

The type of bird bred by the breeder of pedigree layers has drifted further and further away from the standard set up by the specialist exhibition clubs. So much is this so, that in the case of several breeds, particularly White Leghorns and White Wy-

Feather Federation; at Trowbridge by the Wiltshire County Council; and in Ireland at Cork by the Irish Department of Agriculture. In the case of the trials at Newport, Wye and Trowbridge, financial assistance to the work is given by the Ministry of Agriculture.

As a brief indication of the results obtained at a few of the laying competitions the accompanying tables are instructive. (Tables 3 and 4 have been compiled by Mr. H. E. Ivatts, late Hon. Sec. of the National Laying Trials.)

Up to the 1916-17 competition awards were granted upon the basis of the market value of the eggs laid with a varying discount penalty up to 20% upon eggs weighing less than 2 ounces. Subsequent to 1916-17 the competitive value of a hen's production was determined in accordance with the following rule:—

"For the purpose of the test the eggs laid by each hen will be assessed and recorded according to their weight as first or second grade eggs. First grade eggs shall be those weighing two ounces or more. Second grade eggs during the first ten weeks shall be those weighing less than 2 ounces but not less than 1½ ounces, and for the subsequent period of the test not less than 1½ ounces. Second grade eggs shall be accepted as of equal value to first grade eggs, but not more than 100 eggs shall be credited to the score of any hen in Sections 1 to 5, and in the case of Section 6 (Championship) 200 eggs."

The 1915-16 trials held by the Utility Society have a special interest, as 42 of the competitors' pens were retained for a second year in order to ascertain the yield of these birds for their second year. Table 4 shows the results obtained.

The stimulus given by laying trials to the breeding of highly fecund strains of poultry has been enormous. Not only has the spirit of competition set up by the trials urged breeders to devote much time and thought and energy to their breeding operations, but the fact that a win in a public competition is of great value as an advertisement led to the keenest efforts being made by competitors to obtain a high position in the prize list. It is perhaps not too much to say that success in the trials has been in several cases the foundation of many present-day successful stock poultry farms. Ordinary poultry-keepers wishing to buy birds either as a beginning or to improve existing stock apply to a large extent to successful competitors in the laying trials, and a considerable foreign demand at highly remunerative prices is not infrequently the direct result of success in the trials. This is certainly a mark of progress in the egg-producing industry as a whole, in the same way that the increasing demand for pedigree milking stock by the dairy farmer is an indication of progress in the dairying industry. A word of caution, however, may not be misplaced. There may be a danger in focussing attention too strongly on the development—possibly the abnormal development—of one function, or producing weaknesses in the bird in other directions. There is a certain risk of sterility, high mortality in rearing chickens and general lack of constitution in the adult stock. The really skilled breeder will know how to avoid these dangers, but nature is inclined to be severe on attempts to develop abnormal capacity in any one direction. (Our knowledge of the laws of heredity is still very incomplete in spite of the considerable amount of empiric knowledge possessed by some of our present-day breeders. No doubt Mendel's discoveries and the investigations made by Bateson, Punnett, Pearl and others may give material assistance to the elucidation of the many problems involved in the inheritance of fecundity, but in the meantime stock breeders and commercial egg farmers would do well to remember that high individual egg yield may possibly be obtained

dottes, the birds which win in laying competitions are of a type distinctly different from exhibition specimens and are indeed given a distinguishing designation such as Utility White Leghorns in contrast to Exhibition White Leghorns. Apparently the heavy layer develops a type of her own and if, as appears probable, the future demand for stock poultry should be increasingly for birds whose useful qualities, whether for egg or flesh production, have been highly developed, it is obviously desirable that British breeders of exhibition and utility poultry should take counsel together and if possible frame their breed standards to meet present-day requirements. Otherwise, confusion is likely to increase with resulting loss of trade both at home and abroad.

The Irish Department of Agriculture have held annual eleven-month laying trials in Ireland since 1913, and, as the results are published in a form which facilitates comparison, Table 5 is of interest:—

TABLE 5.—Comparison of Results.

Most of the so-called "commercial egg farms," which have become more in evidence of recent years, are stocked with Utility White Leghorns, White Wyandottes, or Rhode Island Reds. The main business of these farms is to produce eggs for consumption though most of them do also a certain amount of trade in supplying eggs for hatching, day-old chicks, and stock birds. One of the largest British commercial egg farmers, however, who maintains a flock of 5,000 layers and rears some 5,000 to 6,000 chickens every year, states that nine-tenths of his produce is sold for direct consumption and that he regards the hatching egg and stock cockerel trade as comparatively unprofitable and troublesome. All hatching and rearing on this particular farm are done with broody hens, no incubators or foster-mothers being used, and this has been the practice for many years. It has proved commercially successful in this particular case, though other egg farmers use mammoth incubators and pipe brooder houses or anthracite stove hovers with apparently successful results. There is little doubt that the capacity for rearing large numbers of chickens with a low percentage of mortality is the crucial test of the commercial egg farmers' skill and management, and much has yet to be learnt regarding the rearing of chickens in large flocks. Considerable differences of opinion exist as to the comparative merits of pipe brooder houses, anthracite stove hovers, brooder houses with small portable oil hovers, outdoor portable brooders, and natural methods. When the pipe brooder system as practised in America was first tried in England many failures were recorded. Since then, however, improvements have been introduced and there is some evidence that the improved form of pipe brooder house may yet become popular in Britain. At least one large breeder has erected a brooder house of this type with a capacity of from 3,000 to 5,000 chickens and excellent results have so far been obtained. The anthracite stove brooder is now in use in considerable numbers, but opinions vary widely as to its efficiency in rearing a high percentage of vigorous well-grown chickens.

Methods of housing and feeding hens kept principally for table-egg production vary considerably. The usual practice is to keep the birds in comparatively large flocks of from 150 to 400 and to house them in open-fronted scratching-ahed houses, the original type of which was probably introduced from America. These houses are not uniform in type, some being 14 ft. deep with special back ventilation whilst others are built only 9 ft. deep and depend for ventilation entirely on the open front. In Lancashire

the open-fronted house is very little used, a span-roofed type with windows low down near the floor being preferred. The amount of run provided for the birds also varies. One well-known poultry farmer maintains 400 layers to the acre but divides the acre into two portions, and whilst the birds occupy one portion, farage crops, such as thousand-headed kale, which the birds later on consume, are grown on the other portion. On another farm the laying-houses are so placed on the farm and the wire fencing so arranged, that the birds can be given access to arable fields, fruit gardens or pasture, as the crops and the season permit.

In methods of feeding, too, there is also wide variation. The dry mash method is practised on certain farms whilst on others the wet mash method is preferred or a combination of the two. On some well-known egg farms large quantities of cooked vegetable food are regularly fed to the layers, whilst on other farms

very little green food is given beyond what the birds gather for themselves on their runs.

From all this it will be gathered that methods are far from being standardized in the poultry industry, and this is indeed not a matter for surprise when the recent development of poultry-keeping as a business is considered. Unlike agriculture, which is man's oldest industry and has been for many years investigated both from the scientific and practical aspect by some of the best brains, there has been little scientific or even practical investigation into poultry-keeping methods in the United Kingdom. For the novice therefore, who may well feel doubtful as to the best system to adopt, the soundest procedure is probably to obtain information as to the methods practised on several successful poultry farms and then to adopt a method which appears to combine the good points of several.

The keeping of poultry in England by urban dwellers, with gardens or even small backyards, and by allotment holders, received a great stimulus during the war, owing to the falling-off in supplies of imported eggs and the necessity for converting all the edible household and garden waste material into human food. It was soon realized that a limited number of laying hens could be maintained under intensive conditions in small backyards and gardens, at comparatively low cost. The necessary labour could be provided within the family, and first-class eggs produced at the point of consumption at much lower outlay than that involved in purchasing inferior shop eggs. Furthermore, eggs so produced were actually on the consumers' premises. Difficulties and expenses of transport did not affect the supplies, provided a limited amount of additional feeding-stuffs could be obtained to supplement the household and garden waste material. This development in urban poultry-keeping would no doubt have proceeded much more rapidly than it actually did had the supply of chickens, pullets, and hens been greater. Unfortunately, however, poultry-breeders were unable to obtain supplies of feeding-stuffs freely and hence were obliged to restrict their breeding operations. Consequently the demand for laying stock by town dwellers could not in many cases be satisfied, or was met by supplies of old hens which gave disappointing results. In any case urban poultry-keeping has taken a firm hold, so much so that local sanitary authorities and town property owners are showing concern as to possible interference with the amenities of properties in urban areas, and local by-laws and clauses in leases which were more

or less ignored in many cases during the war are now being strictly enforced. It is to be hoped that town poultry-keepers will so regard the requirements of hygiene and sanitation in thickly populated areas that no serious cause for complaint with subsequent restrictive action on the part of local authorities may arise, as undoubtedly "backyard" poultry-keeping can give powerful assistance in reducing the necessity for large importations of foreign eggs.

For backyard, allotment and garden poultry-keeping the intensive system of housing is usually adopted, though in some cases where sufficient space is available open or covered runs for the birds may be provided in addition to the house. Under the strictly intensive system the birds are permanently confined to the house which should afford four or five sq. ft. of floor space to each bird. It is essential that the floor of the house be kept dry and some 4 in. to 8 in. of bedding should be provided amongst which grain should be scattered from time to time so as to induce the birds to take necessary exercise by scratching amongst the litter for the grain. The intensive house is usually of a lean-to open-fronted type so designed as to admit as much sunlight as possible on to the floor in the winter months and yet to keep out rain, snow and wind. It may be built of wood, $\frac{3}{4}$ -in. tongued and grooved match-boarding is often used, asbestos sheeting, or even mainly of felt. As a backyard or garden poultry house is often of a more or less permanent nature it is usually more economical in the long run to use sound materials which are likely to need little repairing. A house of this type, which should be high enough to permit of easy cleaning, may be built for six or eight hens in quite a small backyard, and provided it is kept quite clean and no male birds are kept no offence is likely to be caused to neighbours even in a crowded city district. In circumstances such as these, however, it is inadvisable to attempt hatching and rearing, and the egg supply is likely to be more satisfactorily maintained if fresh pullets are purchased at the end of each summer and the hens disposed of which have been kept intensively for about a year, and have temporarily ceased laying and commenced to moult.

If space permit a covered run may be provided adjoining the house, but the floor material, especially if of soil or sand, must be kept scrupulously sweet and clean. The top surface should be raked off and renewed from time to time and occasionally a little disinfectant powder may be sprinkled in the run. Extra accommodation of this sort is, however, not really necessary for laying stock kept under proper intensive conditions for one year only, and most backyard poultry-keepers with limited space at their disposal will find an intensive house constructed on sound lines most suitable for their purpose.

The Sussex poultry-fattening industry, which had become of considerable importance in the three south-eastern counties prior to the war, has become almost extinct owing to the high price, and the difficulty in obtaining supplies, of the Sussex ground oats which were invariably used for cramming the birds. Apart from the fact that it was considered uneconomical in war-time scarcity to use concentrated feeding-stuffs for the production of the highly finished, crammed Surrey fowl, supplies of store chickens were difficult to obtain, feeding-stuffs were very short and were rationed, and, owing to the shortage of fresh meat, chickens found a ready market in almost any condition. Thus the old Sussex fattening industry gradually died out, though of course chickens continued to be reared as far as conditions would permit and were marketed as a rule without cramming or special fattening.

There have been some indications of a revival of the cramming practice, but Irish supplies of store chickens having been diverted for direct sale in London and elsewhere, and poultry-raisers having accustomed themselves to selling their birds for direct consumption without additional fattening, it may be that any general revival of cramming will be long deferred. Much will depend upon the public demand and this will no doubt revive to an increasing extent if supplies of the former high-quality crammed chickens become greater. The practice of trough feeding chickens in fattening coops for a week or so in order to give them a little extra finish is still continued to a certain extent during the late summer, and this practice has much to commend it. Less skill is required than in cramming; it is more economical of feeding-stuffs, and though the chickens cannot be as highly finished as by the crammer, good-quality table birds can be produced which are readily saleable at satisfactory prices.

Like the Sussex cramming industry, the old-established Aylesbury duck-fattening industry, as well as duck-fattening farms outside Buckinghamshire, became practically extinct during the

war, but duck farms were bound to reappear as feeding-stuffs became cheaper and more plentiful. In 1927 the tendency appeared to be to keep the lighter breeds of ducks, such as the Indian Runner, the Khaki Campbell, and the Buff Orpington, for egg production rather than for table purposes, and much attention has been drawn to this aspect of duck-keeping owing to the laying competition for ducks conducted by the Great Eastern Railway Co. with the Utility Duck Club.

For many years the poultry industry received little recognition or assistance from the state authorities in the United Kingdom. Considerable changes in this respect, however, have been in evidence during recent years. State aid has been mainly directed to educational activities, and there are now few counties which do not possess an instructor in poultry-keeping, whose duties consist in giving instruction in this subject by means of peripatetic lectures, classes, and visits to poultry-keepers. Most of the agricultural colleges, dairy institutes and farm institutes also provide regular instruction in poultry-keeping to their pupils, and in some instances—such as at the Harper Adams Agricultural College, Shropshire; the Lancashire County Council School at Hutton; the Glasgow and West of Scotland Agricultural College Poultry School at Kilmarnock, etc.—courses of training are provided for students desiring to specialize in poultry-keeping.

Poultry-breeding centres have been established by the Board of Agriculture in co-operation with local authorities in almost every district in the United Kingdom, for the purpose of distributing good pure-bred utility poultry—usually by the sale of eggs for hatching or day-old chicks to smallholders, cottagers and allotment holders. This scheme has met with much appreciation and success. Table 6 shows the number of distributing stations established in England and Wales and the numbers of eggs and chicks distributed since 1919:—

TABLE 6.—Distribution Stations.

	Egg Stations	Egg & Chick Stations	Chick Stations	Incubating Stations	Total	Total Eggs	Distribution Chicks
1919	156	..	3	4	163	52,980	2,974
1920	122	39	8	4	173	141,611	20,934
1921	138	84	9	4	259 ¹

¹ Includes 24 stations which undertake distribution of ducks' eggs.

It is significant of the interest now taken by the State in the development of the poultry industry that the Ministry of Agriculture and Fisheries has created a separate Small Livestock Branch, on the staff of which technically qualified officers were appointed. One of the chief duties of the branch is to supervise the poultry educational work of local authorities in respect of which grants in aid are made by the Ministry. It is the duty of the technical head of the branch to advise the Ministry on matters relating to the industry.

Valuable work is done in Britain to assist the poultry industry by poultry societies and clubs, such as the National Utility Poultry Society, the Poultry Club, the Northern Utility Society, the Scientific Poultry Breeders' Association, the Midland Fur and Feather Federation, and many others. These clubs organize lectures, demonstrations, laying competitions and shows, and do a great amount of voluntary work in an advisory capacity. In 1920 a central organization known as the National Poultry Parliament was set up mainly through the efforts of Mr. Edward Brown, F.L.S., who was unanimously appointed the first president. This poultry parliament, which meets once or twice a year to discuss questions relating to the industry, is representative of societies, clubs, educational authorities and institutions and trading organizations. The parliament has appointed a smaller executive body known as the National Poultry Council, and one of the first important steps taken by the council was to set up a national examination board to conduct an examination and to award to successful candidates a national diploma, which is intended to be in the main a standard qualification for persons desiring to obtain appointments as instructors in poultry-keeping. (P. A. F.)

POULTRY

139

UNITED STATES

Profound changes took place in the American industry between 1900 and 1920. In 1900 "breeding-birds" and meat were the principal objects of poultry raising and furnished most of the profit. Eggs at that time were a by-product. Conditions had so changed by 1920 that eggs were the principal money producer and meat and breeding birds were the by-products.

Many factors contributed to this change. There had been a greater increase in the population especially in the cities, than in the number of hens kept. Consequently there was a greater demand for meat and eggs, especially eggs. Cold storage facilities and improved shipping methods had raised the average quality of the product marketed and by more nearly equalizing the supply and price, had increased the demand. The spring flow of eggs after the introduction of storage became profitable, although formerly it often had resulted in loss. The per capita consumption of eggs and poultry flock decreased because of the increase in price. The increase in price affected the consumption of meat more than of eggs because substitution of other meats was possible. Eggs, quickly and easily cooked, digestible, containing concentrated vitamins, clean, imparting their flavour and preserving qualities to cakes and pastries, remained in strong demand even at high prices.

During 1920 the total value of products placed the industry among the few of those connected with farming from which the 1920 return exceeded a thousand million dollars. The 1920 census showed more farmers reporting poultry than any other single crop, even apart from the large quantity of poultry raised in towns and villages not covered by the census reports.

Table 7 shows that, relatively, poultry-keeping rapidly declined in the east during the decade 1909-19. The west, especially the Pacific Coast states, continued to increase. The decline in the east was due largely to the high price of feed and the difficulty of obtaining it, particularly during 1917 and 1918, and the decrease in farm population and the number of farms. Opposite conditions obtained in the west. While feed was higher it was easily obtainable and relatively cheaper because of the freight congestion. During the decade there was an increase in the number of farms and farmers in the west particularly on the Pacific Coast. The poultry farms in New England that were making a specialty of producing meat were to a large extent put out of business owing to the increased cost of feed and labour without a proportionate increase in the price of meat during 1917 and 1918. The same was true to a lesser extent of the specialized egg farms and farm flocks in New England and the North Atlantic states. These farms had not returned to normal when the 1920 census was taken, but at the close of 1921 a rapid development was under way.

The general depression in the industry from 1916 to 1919 primarily affected those who were obtaining comparatively poor egg production due to faulty methods of management or to poorly selected or poorly bred stock. The poultrymen who obtained high egg yields made greater profits than for the years 1910-1915. This condition drew the attention of poultry-keepers to the necessity of getting a good egg yield and led to systematic breeding and selecting for egg production. Many farms, particularly those in the northwest, have bred their birds to the point where they are getting an average egg production of over 200 eggs per hen from large flocks of birds. From 1900 to 1915 an increasing number of commercial poultry farms were established primarily to produce eggs. These took the place of the broiler farms, which had been mainly failures. Through these farms and the value of the produce, poultry became a business or industry rather than a side-line for farmers' wives or a hobby for fanciers.

Perhaps the most rapid change that took place in the industry during the period 1910-20 was that in 1910 but few baby chicks were sold, but in 1921 millions were sold to the advantage of the breeder, the hatchery man and the farmer raising the chicks. If the rate of increase of the chick hatcheries for 1918-21 should be maintained until 1930 comparatively few hens then would be used for hatching, and comparatively few hatching eggs would be sold except to the hatcheries.

TABLE 7.—*Chickens on Farms in the United States, 1920 and 1910; and Eggs Produced and Chickens Raised, 1919 and 1909 by Geographic Divisions (from 14th Census Report).*

¹ The figures for both 1919 and 1909 include estimates for farms reporting chickens on hand but no eggs produced. The returns for 1909 included all eggs produced. To obtain figures for chicken eggs alone, deductions have been made for eggs produced by ducks, in proportion to the number of ducks on hand in 1910. Eggs from fowls other than chickens and ducks are considered negligible.

² The figures for both 1919 and 1909 include estimates for farms reporting chickens on hand on the census date but no chickens raised during the preceding year. The returns for 1909 included all kinds of fowls raised. To obtain figures for chickens alone, deductions have been made for fowls other than chickens, in proportion to the number of such fowls on hand in 1910.

³ The products shown for 1919 include chicken eggs and chickens only, while the 1909 figures include the products of all kinds of poultry.

⁴ Chickens 3 months old and over.

In 1900 there were few colleges or experiment stations in America teaching poultry raising or experimenting with it. By 1920 all the states were teaching and most of them were doing experimental work. Colleges and experiment stations have been of great assistance to farmers and poultrymen in showing them better methods. Egg-laying contests have shown the value of breeding for high production and of strains rather than breeds so far as egg production is concerned. The first egg-laying contest in America was at Storrs, Conn., under the supervision of the Connecticut Agricultural College in 1911-2. There were more than 20 contests in the United States and 10 in Canada in 1921-2. The highest average production in any contest was obtained by the Western Washington Experiment Station at Puyallup, Wash., for the year 1920-21. The 365 birds in the contest averaged 214 eggs per hen. The pen of five single-comb White Leghorns which led the contest and made the American record laid 1,384 eggs or an average of 276.8 eggs per hen.

During 1910-20 ornamental breeds and bantams so decreased that in 1921 few commercial breeds were maintained on a large scale. The chief breeds were White Leghorns, Barred Plymouth Rocks, Rhode Island Reds and White Wyandottes. There were also fairly large numbers of Anconas, Buff and White Orpingtons, Brown Leghorns, White Plymouth Rocks, Buff Wyandottes, Black Minorcas, Black Langshans and Light Brahmas.

Table 8 shows that imports and exports of eggs and egg products greatly increased from 1910 to 1920, the imports more

TABLE 8.—U.S. Exports and Imports; Eggs (Shell) and Egg Products, Fiscal Years 1910-20

	Exports	Imports
1910	\$ 1,264,043	\$ 166,859
1915	5,083,825	1,236,889
1920	19,459,187	9,250,021

rapidly than the exports, so that the United States seemed likely to become on balance an importing nation. The exports for 1920 consisted largely of shell eggs and went to Cuba, Canada, Mexico, Panama, England and Scotland. A considerable proportion of the eggs that went to Canada replaced Canadian eggs shipped to England. As Canada has a grading law, its eggs were exported to better advantage. The imports were mostly egg products from the Orient, particularly from China. In 1920 the imports consisted of 1,348,383 dozen of shell eggs, of which over 70% came from the Orient. The egg products amounted to 24,091,008 pounds, of which over 90% came from the Orient. Beginning about 1918 the large packing and egg handling houses began establishing egg-breaking and packing facilities in China and South America, so that in 1921 the imports seemed likely to continue to increase for some years unless tariff changes affected conditions. (O. B. K.)

POWER, SIR WILLIAM TYRONE (1819-1911), British soldier and administrator (see 22.224), died July 24 1911.

POYNTER, SIR EDWARD JOHN, BART. (1836-1919), English painter (see 22.239), died in London July 26 1919. In 1919 he retired from the presidency of the Royal Academy, and was created K.C.V.O.

PREECE, SIR WILLIAM HENRY (1834-1913), British electrical engineer, was born in Wales Feb. 15 1834 and educated at King's College, London. He became a civil engineer but in 1853 joined the Electric and International Telegraph Co., whence in 1860 he reverted to the civil service. In 1877 he was appointed electrician to the Post Office, in 1890 engineer-in-chief and, after his retirement, consulting engineer. He was a pioneer of wireless telegraphy and his early experiments are described in 26.530. He died at Penrhos, Carnarvon, Nov. 6 1913.

PRESSENSÉ, FRANCIS DE (1853-1914), French politician and man of letters, was born in Paris Sept. 30 1853, the son of Edmond de Pressensé (see 22.299). He was educated at the Lycée Bonaparte, and at school had a brilliant career, earning many distinctions. He served on General Chanzy's staff during the war of 1870 and was taken prisoner at Le Mans, but after the war entered the public service. After a short period at the Ministry of Public Instruction, he entered the diplomatic service, and was appointed first secretary at Washington. In 1882 he

returned to France and took up journalism. He was a contributor to many journals, including the *Revue des Deux Mondes* and the *République Française*, and in 1888 became foreign editor of the *Temps*. On the rise of the Dreyfus question (1895) de Pressensé identified himself with the cause of the prisoner. He wrote in support of General Picquart, and in consequence of his advocacy of Emile Zola's cause was struck off the roll of the Legion of Honour. This led to his resignation from the *Temps*, and he came forward as a socialist politician, being in 1902 elected socialist deputy for the Rhone. He was prominent in the debates on the question of the separation of Church and State, and a bill brought in by him formed the basis of the one finally carried by M. Briand. He died in Paris Jan. 19 1914.

De Pressensé published many articles of the greatest interest in the *Temps*, the *Revue des Deux Mondes*, *Aurore* and *Humanité*. He also produced *Le Cardinal Manning* (1896), an interesting study, and a work on Home Rule, *L'Irlande et l'Angleterre depuis l'acte d'union jusqu'à nos jours, 1800-1888* (1889).

PRETORIA (see 22.309).—Pop. (1911), whites 35,942, coloured 18,732, total 54,674; in 1918, whites 41,690. About a mile from the centre of the town on a commanding position on the slopes of Meintjes Kop are the Union Government Buildings, the finest public offices in South Africa. They were built 1910-3, from the designs of Herbert Baker, at a cost of £1,800,000, and consist of three main portions; a large central semi-circular colonnaded building flanked east and west by rectangular blocks. At the junction of each wing with the central section is a domed tower 180 ft. high, and at the end of each wing is a projecting pillared pavilion. A feature of the building is the long low roof, with projecting eaves. The space enclosed by the building is laid out in terraces culminating in an open amphitheatre, in the centre of which is a stone rostrum. The buildings are of South African freestone, on a foundation of Transvaal granite. The laying out and planting of the terraced gardens was not completed until 1920. The principal approach lies 12 ft. below the main terrace, is 80 ft. wide and is planted with trees. Another road leads to the suburb of Bryntirion, where are Government House and the residences of ministers.

The foundation stone of Government Buildings was laid in Nov. 1910 by the Duke of Connaught, and the first public ceremony in the amphitheatre of the building was held in 1915 to celebrate General Botha's conquest of South-West Africa. In 1913 a statue of President Kruger was unveiled in the town. In April 1918 Pretoria became the headquarters of the newly created university of South Africa. One of its constituent colleges, the Transvaal University College (incorporated 1910), is situated in Pretoria.

The State Library and Museum (built 1913) are in Market Street. The former Transvaal Government Buildings, facing Church Square, which is the business centre of the city, are used by the Provincial Council. The Law Courts (completed 1914) are on the north side of the square; the Post Office (completed 1912) faces Church Square and Church St.

The municipality, which owns the sanitary, water, electric and tramway services, spent between 1902 and 1919 a sum of £1,675,000 on improvements, including the provision of a water sewerage system, electric tramways, parks, an open air swimming-bath and a golf course, reputed one of the best in South Africa. The rateable value of Pretoria in 1918 was £7,438,000, its revenue £366,000, and its indebtedness £1,716,000.

PRICES.—In the following article, which should be read in connexion with those under **COST OF LIVING** and **WAGES**, the changes in prices of commodities during the years 1910-20 are considered with special reference to the United Kingdom. An account of the American system for controlling prices in the United States is appended.

(I.) *Wholesale Prices in General.*—The movement of wholesale prices in general is measured by the method of index numbers. The prices of commodities for which definite market quotations for definite grades exist are selected as typical in their changes of prices in general, a year or longer period is chosen as base, the price of each commodity is equated to 100 at the base period and the price in other years expressed proportionately, such numbers being called price ratios. (Thus if the price of wheat in the base period was 60s. and in another year 45s., the price ratio in the latter year would be written as 75.) Then either factors are chosen expressing the relative importance of the commodities as deter-

PRICES

141

mined by the total sum spent on them in a period or some other criterion, and each price ratio is multiplied by the corresponding factor, the sum of the products is divided by the sum of the factors and the resulting quotient is the index number of wholesale prices for that year; or the more important commodities are represented by two or more price quotations and the resulting price ratios are simply averaged to obtain the index number. There are many variants of method and there has been much controversy on every detail of the process; in fact, however, the precision of the result depends not to any great extent on the particular method followed, but principally on (i.) the number of independent prices included and (ii.) on the dispersion of the various price ratios in the year to which the index number refers, so that when prices are moving on the whole in the same proportion the index number is more accurate than when some are moving rapidly upwards and others are stationary or falling. In normal times when changes are moderate it has been shown both from theoretical considerations and by comparing the numbers obtained by various methods that the precision of the method is high, but during the war period the movements were rapid and unequal, the conditions of accuracy were lost and no very precise measurement could be obtained. The object of the method of index numbers is to average away the variations due to the special conditions of supply and demand of particular commodities, and to obtain a resultant which measures the effect on prices of general causes, such as the supply of currency.

It is found in practice that the necessity for restricting price quotations to those of commodities for which the same grade and quality is in the market in large quantities through a long period of years restricts the choice greatly, and limits it to raw materials or articles in an elementary state of manufacture. In some cases the price used is based on the average value of all grades of the commodities (e.g. of wheat, of tea, of coal), imported or exported, but this introduces a possibility of error since the average may change owing to a change in the relative quantities of high and low grades independently of any change in price. The three index numbers of wholesale prices in use in the United Kingdom are the Board of Trade's, the *Economist's*, and the *Statist's* (formerly Sauerbeck's); the first uses average values to some extent and applies factors to the price ratios to allow for the relative importance of commodities, the second and third use market quotations of definite qualities of goods and take a simple average of the price ratios.

Table I. exhibits the general movement in the twelve years before the World War, and shows how little the variation of method affects the result in this period. The year 1903 is taken as the starting point, since it is after the great fall of prices ending in 1896 and the subsequent rise and the inflation of 1900-1, and may be regarded as a normal year.

TABLE I.—Movement of wholesale prices in the United Kingdom 1903-13. (In each case the index number of 1913 is equated to 100.)

Year	Board of Trade Index No.	Sauerbeck's Index No.	Economist Index No.
1903	83	82	79
1904	84	83	81
1905	84	85	81
1906	87	91	88
1907	91	94	93
1908	89	86	83
1909	90	87	84
1910	94	92	90
1911	94	94	95
1912	99	100	108
1913	100	100	100
1914 Jan.-June	—	97	96

Sauerbeck's index numbers for 1903 on the same basis for separate groups of commodities were:—Vegetable food 90; animal food 85; sugar, tea, coffee, 86; minerals 74; textiles 70; sundry materials 83. Wholesale prices had therefore been rising from 1902-13 (with a short inflation and depression in 1906-8), but tended downwards in the first half of 1914.

TABLE II.—*Statist's* monthly index numbers. Average Jan. to July 1914 taken as 100.

<i>Economist</i>	128	167	212	234	244	298	—
Board of Trade	127	164	214	235	261	327	—

Immediately after the declaration of war in 1914 prices began to rise, and with certain interruptions continued to mount up till the spring of 1920, when the index numbers reached their maximum (*Statist* 323, end of April; *Economist* 326, end of March; Board of Trade 357, average of July). Till Oct. 1917 the increases showed a remarkable regularity averaging 2% monthly, equivalent cumulatively to 27% per annum; on this scale the index in the successive Octobers would (each in 1914 106, in 1915 135, in 1916 171, in 1917 217 and in 1918 258, numbers which (except the last) are in close agreement with those shown in the table. This was, however, a definite seasonal movement superimposed on this regularity; in the first three or four months of each year prices moved up with special rapidity, while in the summer the increase was slackened and in some cases was replaced by a fall. The check in the increase in the summer of 1917, following a specially rapid rise, is attributable to the control of prices which by that date was general. From Aug. 1917 prices continued to rise in spite of control till Sept. 1918, but the rise in these 13 months aggregated to only 13% (236 against 213). After the Armistice prices fell slowly for five months, during the season in which in previous years the increase had been specially rapid, but expectations of a permanent fall were not realized; in the year beginning April 1919 the index rose from 224 to 323 or 44%.

From the beginning of the war till July 1919 the *Statist* and *Economist* index numbers are in close agreement, except that the *Economist* shows a more rapid rise for twelve months from Oct. 1916 and less increase in the late autumn of 1917, but there is disagreement as to the dates and amount of the increase after July 1919. At that date the three index numbers agree in estimating the whole increase in five years at 148, 149 or 150%. The following table shows the divergence in subsequent months:—

TABLE III. Monthly index numbers, July 1919 taken as 100.

	Board of Trade	Economist	Statist
1919			
July	100	100	100
Aug.	106	101	103
Sept.	110	102	104
Oct.	115	105	109
Nov.	120	108	112
Dec.	123	114	114
1920			
Jan.	127	120	119

The prices are of course measured in the currency of each country. In every case there is a fall in the last months of 1920.

unobtainable. It is important to emphasize this uncertainty, for it is the fact that exact measurements of general price changes cannot be made in times of disturbance, and indeed it is difficult even to define the quantity we wish to measure; tendencies can be observed clearly, but only rough measurements can be made and fine comparisons lead to error. The maximum level was reached in March 1920 by the *Economist* index number, in April by the *Statist*, in July by the Board of Trade. By Dec. 1920 the Board of Trade index was back at the level of the beginning of 1920, that of the *Statist* at the level of July 1919, and that of the *Economist* at the level of May 1919. The difference is mainly due to the varying proportions given to cereals and textiles, which had fallen rapidly, and to meat and minerals which had fallen little in the three numbers.

Table IV. (from the *Monthly Bulletin of Statistics of the Supreme Economic Council*, vol. ii., No. 5) shows the index numbers for several countries.

(II.) *Wholesale Prices of Selected Commodities*.—When we come to commodities separately, the measurements can be made more exactly subject to the two following qualifications. During the war period the ordinary sources of supply were so disturbed that pre-war kinds and qualities were no longer in the market (in the *Economist* index number only 19 out of the 44 quotations included were not subject to some modification of kind); and a statement of prices is generally taken as meaning the price at which a purchaser can obtain the goods he desires and at which a merchant is willing to sell, but in the time of control and rationing these conditions did not obtain, and the price was fixed by other conditions than those which influence a free market.

Table V. is based on the prices tabulated in the *Journal of the Royal Statistical Society*, July 1920, pp. 640-5, by the editor of the *Statist*. The index numbers have been recast, the average price in 1913 being taken as 100 for each commodity; the totals have been obtained by grouping together the separate entries on the same plan as in the original, but the change in base year affects the results, which thus differ from those given in Table II. in the same way as if the weights had been changed.

It is at once evident that the various prices have not followed the same course; the extremes in 1919 are tin, whose price rose only 28% in 6 years, and Russian flax, where the rise is 323%. This great divergence of itself shows that the general index number cannot have great precision; but in the absence of means of improving it, we cannot do better than take this number (shown in the line "Grand Total" in Table V.) as measuring the general inflation of wholesale prices.

The prices as recorded are the resultants of at least five nearly distinct forces, viz. the general inflation of prices, the conditions

of supply and demand for the separate commodities, the control of supply, the control of prices, the change of quality. In 1915

‡Comparative values.

§Approximate prices. *Nominal prices.

and 1916 the principal increases may be traced to the diminution or difficulty of supply (cereals, sugar, flax) or to acuteness of demand (wool) or to both (timber). In 1917-8 the prices of nearly all commodities whose supply was threatened or for which

the demand was increased were controlled. The quality was changed definitely in the case of flour and indirectly when the prices are averages of several grades as in the cases of meat, flax, leather and timber.

Food.—The price of wheat rose immediately after the beginning of the war, and with it the prices of flour, oats, maize and rice. The prices were checked by the establishment of a government system of purchase at the end of 1916 and by the control of the prices of home-grown cereals in 1917; with this system flour of mixed materials was substituted for wheat-flour and the product sold at a price kept constant and relatively low, by the help of a subsidy beginning in the autumn of 1917. In the case of wheat and flour the subsidy and control continued till the beginning of 1921 but the prices rose; the prices of other cereals increased very rapidly from the autumn of 1919. An attempt was made to control the consumption of oats in 1917-8, otherwise cereals were not rationed. The wholesale price of potatoes was fixed from time to time, the Government undertaking to make good growers' losses, but the price was changed so frequently that the control had little effect.

Early in the war the price of imported meat increased more rapidly than that of home-killed, till in 1917 there was little difference between their retail prices. On the whole the price of meat increased less than that of commodities in general. Prices were fixed in Aug. 1917 and consumption was rationed early in 1918; after the Armistice control was gradually relaxed; but prices of beef and mutton changed very little during the two years after the first fixing of them. The prices of Irish bacon quoted are hardly typical; in 1917 a great quantity of American bacon of inferior quality was bought by the Government, who had difficulty in selling it at a price which covered the cost. The demand for high-class bacon could not be met, and its price after 1917 rose more rapidly than that of butcher's meat. The line in the table relating to imported butter is perhaps misleading since the supply was insignificant, and its inclusion unduly depresses the average; for the records of milk and its products we must depend on retail prices. Taken together the prices of animal food increased at a lower rate than the general average of prices except in 1916-7.

The price of sugar was of course dominated by the cutting off of the continental supply, and its increase was greater than that of any commodity always obtainable included in the table. The Government took over the whole supply at the beginning of the war and issued it at a fixed price; the control continued till 1921. There was no shortage of supply of coffee nor of tea (except in the autumn of 1917), and their prices rose relatively little.

When all food prices are grouped together as in the table, it is seen that they rose till 1917 more rapidly than the average for materials, but that the increase from 1913 to 1918, and to 1919 was the same in the two groups.

Materials.—The prices of different kinds of coal increased at different rates prior to the general control of coal mines which took effect early in 1917; with the stoppage of export of coal the supply was adequate even for the increased use in the manufacture of pig-iron, and the restriction in consumption from 1917 was only necessary to economize labour in the mines. For domestic and manufacturing use the price rose but slowly till 1919 and generally less than for goods in general. Iron and steel began to come under control as early as June 1915 with the initiation of the Ministry of Munitions, and their use was severely restricted for all civil purposes, so that there was no free market for more than three years. The prices were actually fixed in Nov. 1917, a government subsidy being given to steel and to pig-iron makers to meet any extra costs. The subsidies were withdrawn early in 1919 and the price of pig-iron rose from £4 15s. to £8 a ton, the pre-war level having been £2 11s. Reconstruction and repairs, for many years in arrear, caused a great demand for iron and steel, and in July 1920 pig-iron was 320% and steel rails were 283% dearer than in 1914; prices fell slowly in the autumn of 1920 (Birkett: "Iron & Steel Trades during the War," *Statistical Journal*, May 1920). Copper, tin and lead showed no special inflation and were relatively cheap in 1919.

PRICES

Cotton followed an exceptional course. With the cutting off of Germany from the market the price fell considerably in the first months of the war and was below the pre-war level till nearly the end of 1915. Presumably in consequence of the restriction of shipping, a rapid rise began in the autumn of 1916, and at the date of the Armistice cotton was at three times its pre-war price; then there was a perceptible fall for some months, but this was followed by a great increase, the reason of which has not been explained, which brought American cotton early in 1920 to more than four times its cost in July 1914; the reaction from this inflation gave the first indication in 1920 that the general index number was about to move downwards. Both yarn and piece goods rose more rapidly than raw cotton, especially in 1919-20.

The price of wool also fell after the outbreak of war, but the great demand for the Allied armies soon turned the scale and English wool especially became rapidly dearer in 1915. From June 1916 the Government took steps to assume ownership of all the wool it required and to control the rest; the distribution to manufacturers and prices was arranged by an intricate system involving the Government, wool-brokers and manufacturers (*Zimmer: Economic Journal*, March 1918). The price was very high in 1917-8 and rose rapidly in 1919 when the civilian demand for replenishing their wardrobes and households was acute, and the prices of yarn and manufactured goods outpaced even raw materials. There was no definite fall till 1920. As regards flax, the cutting off of the Russian supply and the Government demand for linen in airships caused linen to be practically unobtainable by civilians, and the shortage naturally continued long after the war. Jute and silk were less affected.

The variations in the movements shown under the heading "Miscellaneous" can in general be explained by known conditions of supply and demand. The supply of petroleum proved to be sufficient for war needs. The *Statist* index number is vitiated by the exclusion of rubber. Owing to the development of plantations before the war the supply was even excessive; the price was rarely more than 20% higher than in July 1914 and after the Armistice was lower.

(III.) *Retail Prices of Food in the United Kingdom.*—Accurate and useful statements of retail prices are in general only obtainable with respect to food, in part because most attention has been directed to recurrent and necessary domestic expenditure, in part because it is less easy to define the unit of purchase in the case of clothes and manufactured goods. The cost of other necessary items of expenditure is considered in the article *COST OF LIVING*, and this section deals with food alone.

The following tables show the average prices paid by the working classes in the United Kingdom, the result of the monthly collection of information by the Ministry of Labour (formerly by the Board of Trade) published in each issue of the *Labour*

Gazette, and described in detail in the issue of March 1920. The general movement in retail prices was similar to that of wholesale, that is, a nearly regular increase (23% cumulatively per annum) took place for three years after the outbreak of war, then for more than a year the rise was checked by control and rationing; there was a temporary fall in the spring of 1919, followed by a rise which became rapid in the summer and autumn of 1920 and a fall after Nov. 1920.

TABLE VII.—Average of Retail Food Price-Changes in the United Kingdom as computed in the *Labour Gazette*.
(The average on the 1st or 2nd of each month is expressed as a percentage of the average in July 1914.)

*Second quarter of 1914 taken as 100.

Table VII. shows the average of the movements as combined from the data in Table VI. (together with the prices of fish and eggs) by the Ministry of Labour, each item being given the importance estimated from a pre-war standard budget of expenditure. For the relation of this computation to the cost of living see *COST OF LIVING*. Except for making facile generalizations the detailed table is more important than the summary.

The price of bread rose intermittently, but on the whole rapidly till Sept. 1917, when its price was exactly double that of July 1914. The rate of extraction of flour from grain was controlled from the autumn of 1916, and government regulation flour containing an admixture of wheat, maize, rice and other cereals in varying proportions alone was used in the three years 1917-8-9, and during this period the price is not that of a commodity of constant quality. In Sept. 1917 the Government fixed the price at 9d. for the 4-lb. loaf, became the sole purchasers of the necessary cereals, regulated the price to millers and bakers and met the deficit by a subsidy. The price was raised to 9½d. in Sept. 1919 to meet bakers' increased expenses, and at subsequent dates again raised with the increasing price of wheat till it reached 1s. 4d.; when wheat fell in the latter part of 1920 the subsidy was gradually reduced to zero and the price of bread maintained; in 1921 the price fell, and was 1s. 1½d. from April to July. Flour followed nearly the same course as bread.

The retail prices of meat were determined by the wholesale prices already discussed. Imported meat remained for three and a half

TABLE VI.—Average Retail Prices in the United Kingdom of the Principal Foods as recorded* at the beginning of each month in the *Labour Gazette*.

*The prices from Dec. 1914 to Dec. 1918 are calculated from the percentage changes recorded.

NOTES.—The prices of meat are the means between two entries in each case and not the average prices of the carcasses. They should only be used for comparative purposes, and not taken to be the average price of all meat bought.
In general the records are the average for the commodities as bought in shops and stores used by the working class.

years at 2d. or 3d. a lb. lower than British meat, but since the price of the latter was nearly doubled, the percentage increase of the former was much greater. The Ministry of Food fixed wholesale prices and the retailer's margin in September 1917 and subsequently the distinction in price between British and imported meat was removed. Rationing was gradually introduced, and was nearly universal from April 1918 to May 1919. Purchasers were restricted also to the kind of meat that was available from time to time. During the period of control and till the summer of 1920 prices fluctuated little, but after control was removed imported meat became cheaper than British, and with a rise in the latter in 1920 the pre-war proportion between the two was nearly restored. Home meat was at its maximum (at about two and a half times its pre-war level) in the autumn of 1920 and did not fall at all considerably till after May 1921.

Prior to 1914 the corresponding numbers, for London only, are 1910 and 1911 98, 1912 and 1913 103. (See article COST OF LIVING for further analysis, and for comparative figures for other countries.)

The price of *bacon* rose rather more slowly in the opening years of the war, but rapidly in the summer of 1917 till it was 140% above the pre-war price. In Nov. 1917 importers' and dealers' prices were fixed, and in July 1918 the regulations extended to retail prices; during this period large supplies of generally inferior bacon were received from America, and rationing was only necessary for a few months. The price after being stationary for two years rose during 1920 till it reached three times the level of July 1914.

After 1915 the price of *milk* was markedly seasonal, while before the war it was generally retailed at the same price nearly all the year round. No change took place till the autumn of 1915, when the price rose 1d. a qt., and in the following autumn another 1d., and in neither case was there a fall in the spring; in the autumn of 1917 it reached nearly twice the pre-war price, and in subsequent years fell in the spring and rose in the winter to successively higher points, the maximum (10½d.) being reached in Jan. 1920. Maximum prices were in force from the autumn of 1917 till Jan. 1920, but they were not reached in all localities. The great rise in the price of milk must be attributed to the high cost of cattle food, which was very scarce in the period of restricted imports; elaborate arrangements were made to increase the supply by curtailing the consumption of cream and the manufacture of butter and cheese. Milk was not rationed except by informal local arrangements. Not much attention should be paid to the prices of *butter* and *cheese* after 1916, since during a long period they were not freely obtainable, and the Government having taken control distributed them at prices which would meet their cost. Butter was rationed with margarine.

The price of *margarine* rose little till 1917, while its consumption increased greatly owing to the want of butter. A shortage of supply was felt suddenly at Christmas 1917, and the Ministry of Food took control and presently assumed ownership of the supply of its constituents and the factories in which it was made. The quality was greatly improved, as compared with that in 1914, and its importance as food became very great in view of the difficulty of obtaining sufficient fatty substances from other sources. The price was fixed in Nov. 1917 at 1s. (is. 4d. for oleomargarine) and changed little till the end of 1920. In May 1919 the price was left free.

The whole supply and distribution of *sugar* was taken over by the Government at the beginning of the war and control was continued till 1921. Sugar was distributed through the ordinary channels in such amounts as were available and traders began early to ration their customers. Official rationing (generally at 8 oz. per person) developed in 1917 and its success encouraged the Government to develop the general scheme of rationing meat, fats and some other foods in 1918; rationing of sugar gradually became obsolescent in 1919. The price rose considerably at irregular intervals as shown in the table till in Jan. 1920 it was seven times as dear as before the war.

Potatoes became dear after 1916 and afterwards fluctuated strongly upwards in sympathy with other agricultural produce and the price of manures, and in relation to the supply of each season. The high prices, however, were not universally felt owing to the development of the cultivation of private allotments especially early in 1918.

The supply of *tea* was ample except for a short period in the autumn of 1917. At that date the Government took control of the supplies and provided a uniform blend to be retailed at 2s. 8d. per lb. The rise in price was less on the whole than that of any other commodity shown in the table.

Other less important foods often showed a greater increase in price than those already named, especially since there was a run on them during the time of restriction and shipping facilities were given rather to the more necessary imports. Eggs in particular became scarce and dear owing to the failure of the European supply and the scarcity of poultry food.

No general comparison of wholesale and retail prices is possible, for want of adequate records of the wholesale prices of manufactured goods and of retail prices of articles other than food. In the case of food, however, the figures are sufficiently typical and accurate to allow of a general comparison, but not to permit accurate detailed measurements. The two index numbers shown depend on nearly the same range of foods, but the broad subsidy lowers the retail prices by about 10 points in 1918-20.

*July 1914 for retail prices.

In Table VIII. the retail prices for the first quarter of each year are the averages for the 1st of Feb., March, April and so throughout the year. Wholesale and retail prices include those of controlled goods, and in the case of wheat, flour and bread are affected by the bread subsidy. The table shows that retail prices rose in sympathy with wholesale prices during the first three years of the war, but the rise on the whole was less, and the accelerated rise in the spring of each year was only marked in wholesale prices. As prices became more and more rigidly controlled in 1917, and some commodities were rationed in 1918, wholesale prices fell or remained nearly stationary, while retail prices rose very slowly.

(A. L. Bo.)

PRICE-CONTROL IN UNITED STATES.—During the World War price-fixing agencies in the United States were numerous, and the arrangements made were often informal. Many prices were controlled indirectly; but when this control was to any degree international the result was a "fixed price."

Prices were more or less formally fixed by various departments or branches of the U.S. Government for at least 110 important products, each of which required a separate price-fixing operation. This was exclusive of repetitions or renewals at later periods, which often involved as much work and study as the original decisions. The following is a partial list of products for which prices were fixed by some government agency or sanction. They are arranged in general in the order in which the prices were fixed, although no pretence to accuracy in this regard is claimed. Food products are not covered in detail, and no attempt has been made to mention them in order:—

Hides	Castor oil	Copper, ingot, electrolytic
Coal, bituminous	Aluminium	Copper wire
Coal, semi-bituminous	Coal, anthracite	Iron ore
Pig iron	Coke	Nitric acid
Steel plates	Copper	Cotton linters
Steel, structural	Molasses (imported)	Cotton goods
Wheat	Manila fibre	Cotton yarns
Ship timbers	Retail lumber (eastern cities)	Denims (Mass.)
Pine, yellow	Platinum	Drillings (Mass.)
Steel billets	Hemlock	Ginghams, (Amoskeag)
Sugar	Pine, white	Print cloths
Sardines	Spruce, eastern	Sheetings, bleached
Bar iron	Paper, newspaper	Sheetings, brown
Pipe, cast-iron	Manganese ore	Hemp

Steel rails	Sashes and doors	Tickings (Amoskeag)
Nickel	Linters (munition)	Flour, wheat
Tin plate	Quebracho extract	Rice
Wire, barbed,	Cement, Portland	Building tile
galvanized	Sulphur	Crushed stone
Wire, plain,	Rubber	Sand and gravel
annealed	Wool	Lead
Ammonia	Acetate of lime	Charcoal
Douglas fir	Quicksilver	Leather, sole
Arsenic	Iridium	Glycerine (dynamite)
Ammonium	Hogs	Cottonseed meal
sulphate	Leather, harness	Cottonseed oil
Alcohol, wood	Prunes, California	Wool grease
Acetic acid	Raisins, California	Burlap
Nitrate of soda	Carbon tetrachloride	Tin, pig
Silver	Formaldehyde	Tree nails, locust
Zinc, grade "A"	Chlorine gas, liquid	Cotton compress rates
Zinc, sheets and	Toluol	Birch logs
plates	Phenol	Brick, common
Binder twine	Picric acid	Wallboard
Castor beans	Sulphuric acid	Food products

Without attempting a complete list, it may be stated that food products whose prices were regulated included flour, bread, sugar, live stock, meat, poultry, dairy products (including retail milk prices), oleomargarine, cottonseed and its products, canned foods, dried foods, rice and rice flour, feeds and coffee. The prices that were first formally fixed by the Government fall chiefly in the basic raw-materials group. A more shortsighted policy might have begun by regulating prices of articles which figure most conspicuously in public consumption.

In some cases prices were fixed for Government purchases alone, for example, nickel, quicksilver, sulphuric acid, cement, New England spruce and other lumber. In others the prices were fixed for the Government and made available to the public in a contingent way; for example, in the case of hemlock lumber it was provided that any quantity of the commodity which, in the judgment of the lumber director of the War Industries Board, could be released for the commercial market might be sold to the public, subject to the maximum price fixed for the Government. In still other cases—for example, copper and raw sugar—purchases by the Allied Governments were included in the scope of price-fixing for the U.S. Government; and in a few instances, as purchases for the use of the railways of the United States, the prices were specifically fixed, although they did not apply to the public. Prices were sometimes fixed for single branches of the Government, as in the case of oil products for the navy and cow-hide splits for the quartermaster's corps of the army. Prices were even fixed by the U.S. Government to apply to purchases by the Allied Governments only, as was the case with fuel oil, gasoline and kerosene.

The President, however, early took a firm stand for the principle that prices charged by producers should be the same to the public and to the Government, and, with the exception of prices on certain purchases made by Government departments, rapid progress was made during 1918 in carrying out this policy. Thus the prices fixed for pine, fir lumber and cement, which at first applied only to direct Government purchases, were extended to the public. It proved to be highly important as a practical matter that prices under similar conditions of purchase should be the same to all. The existence in the commercial market of prices that were higher than those paid for Government purchases made it difficult for the Government to secure prompt deliveries. Moreover, such a situation often defeated the purpose of price-fixing, because large purchases might be made by private concerns producing more or less directly for the Government.

The period of price-fixing began about the middle of 1917, and came to a nearly complete standstill with the signing of the Armistice. Among the earliest commodities to be affected by the price-fixing activities of the Government were lumber, coal, wheat, sugar and canned foods. Lumber prices for the Government alone were fixed by arrangement with the Council of National Defense on June 18 1917, and approved by the Secretary of War; coal prices for the navy were fixed on June 19 1917. The Food and Fuel Control Act on Aug. 10 1917 set a minimum price on the wheat crop of 1918. Bituminous coal prices at the mine were fixed by executive order on Aug. 21 1917. Nine days

later came the President's announcement of a \$2.20 basic price on wheat "to be paid in Government purchases." The price of copper was fixed in September. Relatively few prices were fixed after Nov. 1918, although those fixed prior to that time extended well over into 1919. Prices, as fixed, were allowed to expire in spite of the fact that in several important cases the representatives of the industry concerned asked that the existing price be continued. On Dec. 11 1918 the War Industries Board issued a statement to the effect that, since it would cease to function after Jan. 1 1919, no new price agreements would be entered into by the Price-Fixing Committee and that all prices theretofore fixed would be allowed to expire by limitation. Several commodities, the cost of which had not been immediately ascertainable, had been taken in large quantities by the Government at prices subject to later determination. For example, during the latter part of Jan. and the early part of Feb. 1919, the Price-Fixing Committee of the War Industries Board fixed prices on common brick and on wall board. Inasmuch as the Food and Fuel Administrations depended for their powers upon the Act of Aug. 10 1917, which applied "during the war," they functioned longer, but became practically inoperative early in 1919.

Of the various agencies through which prices were fixed the following are without doubt the most important: Congress, which by direct legislation fixed a minimum price for wheat and for silver; the President, acting under authority granted by Congress, who fixed prices for coal and wheat; the War Industries Board, created by the President July 28 1917, under authority from Congress, which Board through its Price-Fixing Committee fixed numerous prices from Sept. 1917 to Nov. 1918 (as late as Jan. and Feb. 1919 several cases of price-fixing for commodities bought at tentative prices were awaiting cost determination); the U.S. Food Administration, established in Aug. 1917, which fixed prices of hogs, meat, flour, sugar, binder twine, etc.; local food administrators and sub-agencies, such as the Sugar Equalization Board and the U.S. Food Administration Grain Corporation, which fixed many prices; the U.S. Fuel Administration, established in Sept. 1917, which fixed prices of coal, coke, etc.; the War Trade Board, which fixed prices of rubber, quebracho extract and manila fibre; the Federal Trade Commission, which fixed the prices of newsprint paper; the Emergency Fleet Corporation of the U.S. Shipping Board, which fixed the price of ship timbers and locust tree nails; the U.S. Shipping Board which fixed ocean freight rates; the International Nitrate Executive Committee, which fixed the price of nitrate of soda; the Food Purchase Board, which fixed prices of canned foods, etc., for the army and navy; various army and navy departments, which fixed prices of gasoline and fuel oil, zinc oxide, automatic sprinklers, sashes and doors, castor oil, etc.; the Appraisal Boards of the army and navy, which fixed prices in cases of dissent from prices named in commandeering orders; and the U.S. Railroad Administration, which took steps to fix reasonable prices of locomotives and cars. As time went on a tendency toward greater uniformity and centralization of procedure developed within the price-fixing mechanism. This tendency was seen in an increasing amount of work thrown upon the War Industries Board and the Federal Trade Commission, the former naming a price based largely upon the cost findings of the latter.

In initiating price-fixing no systematic plan was followed and prices were at first fixed sporadically. Various Governmental powers were resorted to and were applied by numerous agencies, using diverse means for carrying out the decisions or agreements which they reached. In some cases prices were fixed under special authority, conferred directly by Act of Congress, and limited by the provision of such Act to specified commodities. Thus by section 14 of the Act of Congress of Aug. 10 1917, already referred to, the President was empowered to fix "a reasonable guaranteed price for wheat." Accordingly on Aug. 30 the President, acting upon the recommendation of a committee appointed by himself, promulgated a price of \$2.20 per bus. for No. 1 northern spring wheat at Chicago. The same law, commonly known as the Lever Act, authorized and empowered the President to license importers, producers or distributors of "any necessities, in order to carry into effect any of the purposes of this Act"; and, if he found unreasonable any storage charges, commissions or profits, to revoke licences and make findings as to reasonable profits, etc. Section 10 of the Act authorized him to requisition necessary foods, feeds, fuels and other supplies. Section 11 gave him

power to purchase and sell at reasonable cash prices wheat, flour, meal, beans and potatoes. The power under this Act ran to the President, and the Fuel Administrator and Food Administrator acted under "executive orders." On the other hand, the War Industries Board acted under less specific authority proceeding from the general war powers of the President. Thus the prices fixed for steel, copper, lumber and other commodities by the Price-Fixing Committee of the War Industries Board were in theory approved by the President before being publicly announced. In some cases, however, such as retail lumber prices in certain eastern cities, the prices were announced without formal approval by the President.

The means of enforcing prices when "fixed," whether determined by the price-fixing agencies or reached by agreement with the producers, were various, ranging from appeals to the patriotism of the trade to commandeering orders. In most cases there was in the background the possibility of the Government's taking over the industry; and in not a few the army or navy did commandeer plants or stocks of merchandise. In such cases a price was named which was subject to adjudication, first by the Board of Appraisers and then, upon appeal, by the courts. On Dec. 24 1917 all wood chemicals (acetic acid, alcohol, etc.) were commandeered for a period of six months and later the commandeering order was extended to cover the second half of 1918. Apart from purchases on army or navy account, however, price-fixing was effected chiefly by "licences" and control of "priorities." The Food Administration and the Fuel Administration, under the Act of Aug. 10 1917, put in force extensive systems of licensing, under which unlicensed producers and distributors were not allowed to engage in business, and licences were revoked, if the regulations were disobeyed. The War Trade Board also licensed importers of certain articles on condition that the prices which it fixed should be observed. The administration of priorities proved to be a major element in the price-fixing programme, and involved many important questions. Toward the end of 1917 a priorities division was established within the War Industries Board and a priorities commissioner placed at its head. Representatives of the Fuel Administration, the Railroad Administration, and the U.S. Shipping Board were placed upon a Priorities Committee. The War Trade Board, the Food Administration, and the army and navy were also represented. The Price-Fixing Committee of the War Industries Board and the Priorities Committee worked in harmony. This was of the utmost importance, as it made possible a substantial degree of unity of policy among the different Government purchasing departments; and, through the power of the Priorities Committee over fuel and transportation, pressure could be brought to bear upon a recalcitrant business concern for the purpose of compelling it to adhere to fixed prices. The Priorities Committee undertook whenever necessary to administer priorities in the production of all raw materials and finished products, save food, feeds and fuels. The distribution of fuel was, of course, under the supervision of the Fuel Administrator, and transportation service under the U.S. Railroad Administration, but the Fuel and Railroad Administrators were guided largely by the "preference list" issued by the Priorities Committee and by the recommendations of the division chiefs of the War Industries Board, and on the whole came to work in close relation to the committee's general policy. The Priorities Committee, then, exercised a general function of adjusting production to the needs of the nation at war by allocating the limited supplies of fuel and basic raw materials, and its powers were sometimes used as a club to reinforce the authority of the Price-Fixing Committee in particular cases. The Army and Navy Appraisal Boards were called to pass on prices in the case of commandeered orders issued for the requirements of those departments. When a commandeered order was to be issued the practice developed of having the chief in charge of that division of the War Industries Board which dealt with that commodity approve the order in which the price was named. If, as was frequently the case, the producers of the commodity were not satisfied with the price, the matter was brought before the Appraisal Board. It is important to observe that those members of the Price-Fixing Committee who represented the army and navy were also members of the appraisal boards of these two departments.

Various methods of applying price control were tried. Prices may be fixed both directly and indirectly. As a rule, each commodity the price of which it was desired to fix was taken up directly and a specific price made for its purchase; but in some cases reliance was placed upon indirect control of the price of one commodity through direct control of the price of another. A most interesting and important phase of indirect price-fixing activities lay in the attempts to restrain prices by controlling consumption, as in the cases of tin, platinum, coal, sugar, wheat and meat. These efforts culminated in rationing in the case of sugar and the requirement of purchase of substitutes in the case of wheat or flour. Steps were taken, also, to prevent waste and to improve methods of production, for example, cleaner threshing of wheat. Most of such "conservation" measures are to be approved without reserve. Closely connected with the conservation phase as seen in control of demand, rationing, etc., were stabilization and pooling. But pooling, while partly used to facilitate rationing (as in the case of sugar), may also be used to keep prices up, either locally or throughout the entire market. In at least three cases, wheat, sugar and tin, the Government entered upon a pool-

ing programme for the purpose of stabilizing prices. Stabilization is a term which implies mixed motives, a considerable part of its purpose commonly being to maintain or keep up prices, at least in a part of the field. This was the case with the Sugar Equalization Board and the tin pool, and the Government's Grain Corporation.

The degree of precision with which prices were fixed varied widely from commodity to commodity, ranging from a loosely determined maximum price to a careful determination of the definite price to be charged for a particular commodity in the case of a particular purchase. As a rule, only maximum prices were fixed, although in a majority of cases the price named as a maximum was the one which actually prevailed. This was not infrequently taken for granted by the price-fixing agency. In some important cases, however, the actual market price fell below the maximum named by the Government. This was true of zinc plates and sheets and certain kinds of lumber. Also, in the case of rubber, a price was named by the War Trade Board as a maximum, which was considerably higher than the market price. As has been already noted, a minimum price was fixed for wheat, the reason being that it was desired to guarantee the market in this case and thus encourage production. The price of hogs was fixed on the basis of a positive minimum after the failure of the attempt to maintain the price on the basis of a fixed ratio to corn. Wheat also furnishes a case in which both a maximum and a minimum price were specifically fixed. Obviously a result similar to that obtained by naming a price may be gained by limiting profits or gross margins. Thus, an effort was made to restrict the profits of the meat-packers to 2½% on sales, and in the case of the five largest packers a maximum margin on meat of 9% on investment was named. The flour millers were limited to a profit of 25 cents per barrel. Dealers in cotton-seed and peanuts, both ginners and others, were limited, beginning July 1 1918, to a margin of \$3.00 per ton over cost (not replacement value). This method was also largely used by the Fuel Administration in an attempt to regulate the price of coal to consumers, and in Sept. 1917 this agency announced its plan for fixing the maximum gross margins of retail dealers in coal and coke. Each dealer was authorized to add to the average margin for 1915 between his delivered cost price of coal or coke and the price charged consumers, 30% to cover increased expenses provided the gross margin thus arrived at did not exceed his average for July 1917. Fixed rates of commission or margins of profit were imposed also on dealers in newsprint paper, retail lumber and other commodities.

In addition to the above methods, there was the attempt to fix retail prices directly by publishing fair prices, as was done for groceries by the local "price interpreting boards" set up by the Food Administration. Price-fixing by restricting margins passed into the realm of hopes and aspirations in such cases as the earlier regulation of the lake-forwarders by the Fuel Administration, and the cotton-ginners by the Food Administration, for in these cases the producers were merely urged to charge "reasonable" prices. Much the same may be said of the somewhat tentative moves made by the Oil Division of the Fuel Administration toward fixing the price of petroleum and its products. In July 1918 the Oil Director made some proposals with regard to fixing the differential between the prices of crude and those of refined products; and in Aug. he announced a plan to stabilize the price of crude oil, stating his belief that this would prevent radical changes in the price of refined products. It does not appear, however, that the plan had any appreciable effect.

From the foregoing it would appear that there were three chief types of price-fixing:—(1) *maximum prices*, in the case of basic staples which had wide public interest, often recognized as "pegged" prices when any scarcity or rapidly advancing cost existed; (2) *definite prices*, (a) to encourage production by guaranteeing returns, (b) Government purchases (direct or indirect) in the nature of single transactions; (3) *margins*, (a) absolute amount per unit, (b) percentage on sales, cost, or investment; this method being used when it was desired to cover the distribution of products, the marketing of which was not integrated with manufacture. The minimum price, strictly speaking, was the exception, but is logically associated with the definite price, which is both maximum and minimum.

Another distinction of some importance in fixing prices depended upon the place at which the price named was to apply. Some prices were made on an f.o.b. factory basis, while others were on a delivered basis. The practice prevailing in the industry was partly followed. The tendency, however, was to fix prices on an f.o.b. factory or mill basis, a natural tendency when the price is based on cost. In a majority of cases, prices came to be made f.o.b. the producer's plant. In many cases, however, prices were quoted f.o.b. some market basing point. This was notably true of copper, which was always quoted f.o.b. New York, although the metal was secured from mines in Michigan, Montana and Arizona, and refined at various seaboard points. In the case of commodities produced in several competing areas there was often a tendency to quote prices on a delivered basis. Prices delivered were fixed for New England spruce,

PRICES

Pennsylvania hemlock, cement, hollow building tile, iron and steel scrap, and oil products for the navy. The situation in the case of hollow building tile furnishes some explanation of this tendency. The chief producing area for this commodity was centered in Ohio, while there were other producing territories in the south, in New Jersey and elsewhere. In order to stabilize market conditions and to divide the market, the representatives of the industry desired to fix prices on a delivered basis. In this way, by fixing a delivered price sufficiently low, the low-cost producers in Ohio were prevented from coming too far east with their product; while, if the price had been fixed f.o.b. the plant, there would have been no limit to the area covered by the low-cost producer, except cost of freight and desire for profit. Had the war continued much longer, there can be little doubt that adjustments in railway rates would have become an important part of the price-fixing programme. Special railway service was given in a number of instances as a direct part of price-fixing, as, for example, the arrangements made to furnish transportation to the Douglas fir lumber mills for the purpose of relieving them of accumulations of low-grade lumber. In the case of price-fixing for manganese ore produced in the United States, an integral part of the scheme was the application of special railway rates.

When a controlling part of the supply of any given product is produced by concerns which are not completely integrated, especially as to the earlier stages of the industry, it is practically necessary, in price-fixing, to control the price of the chief semi-finished products; but when a controlling proportion of a product comes from producers who are more or less completely integrated, this necessity does not exist, although some protection may be required for independent producers in the earlier stages. Also when the object is to protect the consumer of products which are distributed by separate wholesale and retail agencies, it is necessary to control the wholesale and retail prices as well as the price f.o.b. factory or mill.

Prices were fixed for various periods of time, but in general it may be said that on account of changing conditions the periods were short. Perhaps the period most frequently chosen was three months. A much shorter period would have created too much risk and uncertainty in marketing, to say nothing of the strain upon the price-fixing machinery; while a longer period was not, as a rule, desired by the representatives of the industries, especially during a period of increasing costs. Various exceptions might be cited, such as the case of wheat, in which the price was fixed for the crop of a given season. The prices

of meat and coal were fixed for indefinite periods, and the same was true of manganese ore. Various bases for determining the reasonable maximum price to be fixed were used, but it may be said that, on the whole, the prevailing tendency was to fix prices on the basis of cost, a reasonable allowance being added for profits. In this connexion the Federal Trade Commission did important work in ascertaining from the books of the producers the actual cost of production and the investment.

In the ordinary case of price-fixing, the gist of the method used by the Price-Fixing Committee was as follows:—First, some estimate was made of the probable quantity of the product wanted, which, of course, involved a knowledge of the stocks on hand. Second, the quantity which each producer could turn out was ascertained. Third, each producer's cost of production was computed for the most recent period available. Fourth, the average investment involved in the production of the commodity was determined and reduced to the basis of investment per unit of product. The first three of these items bear directly upon the determination of the representative or marginal producers for price-fixing purposes. The fundamental question in fixing prices that are based on cost, is the determination of what may be called the "marginal cost." This cost may be explained as follows: it is frequently the case that when the several individual costs for a group of producers are accurately ascertained and are ranged in their order from low to high, there will be a variation among them of 100%, the high cost being double that of the low cost. Ordinarily the bulk of the production comes from those producers whose costs are below the average, though this is not always the case. It does not follow, however, that the average cost gives the basis for a fair price. If 25%, or even 10%, of the production comes from high-cost producers and the entire output is needed, the average cost cannot be the basis of price. It is true that in many cases prices were fixed on the basis of average cost, both by the War Industries Board and by other price-fixing agencies; but as time went on methods were perfected, and the practice of taking a "representative cost" developed. This representative cost was very similar to what the economist calls the marginal cost, meaning the cost at which the highest-cost producer is able to produce without loss at a given price.

Of the conditions which facilitate the determination of a reasonable marginal cost for price-fixing, a knowledge of the requirements of the market, or in war-time a knowledge of the needs of the Government and its agencies, is most important. Price-fixing in the United States was handicapped by uncertainty as to the quantity which it

was desired to have produced, which uncertainty was in some cases due both to ignorance of the available stocks and to uncertainty as to future requirements. While prices were generally fixed on the basis of cost, there were necessarily many exceptions. Sometimes no costs were available. Sometimes cost was only partly available as a basis, as in the case of "joint products" and of products for which complete cost data did not exist. Sometimes, again, no effort was made to use cost, as in the case of substitutes whose prices were fixed on the basis of the commodity in the place of which they might be used. In a few instances the price was fixed without regard to cost, merely on the basis of preexisting prices, such prices being taken for what was presumably a normal period. Perhaps the chief difficulty in most cases was to ascertain a fair return on investment. This phase of the matter was never satisfactorily dealt with by any U.S. price-fixing agency during the war. The Federal Trade Commission in connexion with its cost findings frequently reported to the Price-Fixing Committee of the War Industries Board a figure representing the investment, but time did not permit the careful investigation that would have been necessary to ascertain the actual money invested, nor was the attitude of the price-fixing agency, as a rule, one which favoured the strict construction of "investment." In general, it may be said that in a majority of the price-fixing operations of the War Industries Board, some consideration was given to the estimated investment, and that in such cases the figure used was one which lay somewhere between the book value claimed by the companies concerned and the actual net investment made. On the other hand, a majority of the price-fixing operations of such agencies as the Food Administration appear to have been made on the basis of a margin (interest and profits) per unit of product, determined upon with reference to past experience. And of course, exceptions to any usual practice were at times necessary.

In general there were three chief purposes in fixing prices: (1) to secure production of needed commodities; (2) to prevent social unrest by checking profiteering, coördinating food prices and wages, and stabilizing industrial conditions; (3) to assure Government economy of purchase. The greatest success was attained with regard to the first purpose. The accomplishment of the second, which was more vague, is difficult to measure, but appears considerable. The most that can be said concerning the third is that things might have been worse had there been no price-fixing.

The table on page 148 shows the yearly and quarterly average prices of important articles whose prices were regulated.

On the whole, it may be said that price-fixing in the United States suffered from the lack of a programme. No adequate study was made of interrelations between commodities or of the various complicated factors affecting demand and supply. No general principles were formulated. Too frequently, each step was taken up as a separate proposition. Much trouble would have been saved by a better understanding among the different price-fixing agencies and by the adoption of certain broad fundamental principles, such as the basis for determining marginal cost and the basis for determining investment. There should have been a general board of strategy to supervise the entire price-fixing programme and to coördinate it with the Government's fiscal arrangements and with the various steps taken to control the production and consumption through priorities and rationing. Some progress was made in this direction, but it remains true that the price-fixing operations were not sufficiently correlated with taxation and borrowing (inflation) on the one hand, and with rationing and priorities on the other. (L. H. H.)

PRINCE EDWARD ISLAND (see 22,344).—The pop. of this Canadian province in 1911 was 93,728, having sunk from 100,078 in 1891. It is the most densely populated province in Canada, with 42.92 persons to the square mile. In 1911 the origin of the people was: Scots 36,772; English 22,176; Irish 19,900; French 13,117; all other nationalities 1,763. Charlottetown, the capital (pop. 11,198 in 1911), standing on one of the best harbours in America, is celebrated as the birthplace of the Canadian Confederation, the first conferences having been held there in 1864.

The Legislative Assembly is composed of 15 councillors elected on a property qualification, and 15 members elected on a popular franchise. The Executive Government consists of nine members.

The superintendent of education acts as secretary to the board and administers the system through school inspectors. In 1920 there were 468 schools, 597 teachers, and a total enrolment of 17,861 pupils; the expenditure was \$268,547 in 1919.

Prince Edward Island has been aptly described as the garden province of the Dominion, more resembling an English shire than a Canadian province. The population is almost entirely agricultural, and practically the whole island has been cleared and brought under cultivation. The soil of the island is best suited for oats and potatoes, which are the staple crops. Wheat is grown for local purposes only. Maize, for fodder, and barley are grown. Cattle and hogs flourish. The total value of field crops in 1920 was \$18,330,490. Poultry-raising and dairying are extensively and profitably carried on. Beef and bacon, as well as fruit, poultry, butter, cheese, eggs and potatoes, are exported in large quantities to neighbouring provinces, Newfoundland and the New England states. Coöperative dairying was begun in 1891 and the growth of the industry has been rapid. A new source of revenue began in 1910 with the breeding of black foxes and the industry of fur-farming was developed. About \$10,000,000 had already been invested in this industry in 1918, in which year the sale of fox pelts realized over \$750,000. In 1919 300 fur ranches sold skins and live animals to the value of \$1,500,000, and in 1920 there were approximately 11,000 pairs of black foxes on the ranches of the island.

The once celebrated Malpeque oyster has almost become extinct through disease. The lobster industry is also on the decline. The value of the fisheries in 1919 was \$1,536,844, the catch including cod, herring, mackarel, oysters and lobsters. The men employed in the industry numbered about 6,000.

No mining is carried on. Manufacturing is connected chiefly with the preparation of foods such as butter and cheese. Pork-packing and lobster-canning are large and growing industries. The value of manufactured products was \$3,136,470 in 1911.

The strait of Northumberland separates Prince Edward Island from the mainland, the distance across varying from 9 to 31 miles. At the narrowest point a railway-car ferry established in 1918 by the Dominion Government connects the Canadian National railway system of the mainland with that on Prince Edward Island, and affords continuous connexion summer and winter across the strait. This is the principal highway of transportation to and from the island province, but the ferry service is occasionally interrupted by ice and the substitution of a tunnel has been advocated. (W. L. G.)

PRINCETON UNIVERSITY (see 22,347).—In Sept. 1910 President Wilson accepted the Democratic nomination for governor of New Jersey and resigned the presidency of the university. In Jan. 1912 Prof. John Grier Hibben, of the faculty, was elected president. His administration was marked by further development of student self-government, the conducting of discipline and general student activities and the regulation of athletics being in 1921 shared by undergraduate representatives and university officers. Especial attention was paid to the scientific safeguarding of student health and physical fitness by careful periodical examinations and required supervised athletics. The potential effectiveness of the alumni organization was increased by the formation of a National Alumni Association, whose working administrative centre was the Graduate Council of about 100, representing the graduate classes, the alumni associations, and different regional districts of the country. The national character of the university was expressly recognized by the addition of regional trustees to the governing board, and also by the establishment of a large number of regional competitive scholarships.

On the scholastic side, the entrance requirements and the undergraduate curriculum were completely revised. To put the university into closer touch with American secondary education, especially the high schools, Greek was no longer required (although strongly advised) for the A.B. degree. The Litt.B. degree was discontinued. The elective principle was broadened so as to bridge the gaps between preparatory school and college, and underclass and upper-class years, giving the student in his underclass years a broad general training in subjects deemed fundamental to real education, and in his upperclass years requiring him to follow continuous work in one of three divisions of studies, the literary-philosophical, the historical-economic, or the mathematical-scientific. The regulations governing admission to the graduate school, and in particular to candidacy for the competitive fellowships, the awards of which depend entirely on scholarship and ability, attracted to the school an increasing number of select advanced students in liberal studies. The erection of the residential graduate college in 1913 rendered permanent what had previously been an experimental and, in America, an unique feature of the Princeton graduate school, namely, the provision of adequate living quarters for graduate students, who there shared a common scholarly life amid attractive conditions. The graduate college accommodated in 1921 about 100 students.

During the World War over 5,000 undergraduates and graduates were in Service; about 3,000 receiving commissions, and 284 receiving 293 decorations and citations. The honour roll of those who gave

up their lives numbered 149. The entrance atrium of Nassau hall was converted into a memorial to these men, and a scholarship has been founded in memory of each. During the war nearly half of the faculty was on leave of absence, either in military and naval service, or in the scientific war service of the American, British or French Governments. The student body was cut more than half; buildings were occupied by a Government school of aviation and a naval paymasters' school, while the laboratories were turned over to Government use. With the institution of the student army training corps, and the naval training unit, virtually the entire university and its equipment were devoted to national purposes, the number of civilian students being about 75, rejected from service for physical disabilities. After the return of peace, effort was concentrated on increasing the inadequate endowment of the university, and the sum of over \$8,000,000 was raised. A bequest from the late Henry C. Frick, not yet received in 1921, was expected to amount to about \$5,000,000. In the year 1920-1 the faculty numbered 213, the undergraduate body 1,814, the graduate students 149, as against, in 1909-10, 169 faculty members, 1,266 undergraduates and 134 graduate students. Besides the graduate college, which includes the Cleveland tower, a national memorial to President Grover Cleveland, a trustee of Princeton, the buildings erected between 1912 and 1921 were Holder hall (a dormitory), Madison hall (the university dining halls, where all underclassmen are required to take their meals), Cuyler hall (a dormitory), the Palmer Memorial football stadium, and the University boat house (headquarters of the rowing activities of the university). In May 1920 Dickinson hall and Marquand chapel were destroyed by fire. (V. L. C.)

PRISONERS OF WAR (see 28.314*).—The procedure laid down by international agreement for the treatment of Prisoners of War under the Hague regulations was tested during the World War under unprecedented difficulties. These arose not only from the passions and prejudices inevitably engendered in the course of such a vast conflict between the entire manhood of the nations concerned, but also from the facts that unexpectedly large numbers of combatants were taken prisoners, and that the captors had to deal with men of different nationalities, of varying characteristics and with widely different views as to the accommodation and food requisite for a prisoner of war.

Probably few people realized during the war how vast was the number of combatant prisoners taken by one side or the other, or how small was the proportion of the British prisoners to the whole number. Though the final figures cannot be given otherwise than approximately, it is certain that they amounted to several millions. To name only the principal belligerents (excluding Russia), Great Britain claims to have taken just under half a million, France just over that number, Italy nearly one million, Germany two and a half millions and Austria nearly one and a half millions. With regard to Russia the numbers have never been even approximately ascertained, but some idea of them may be gathered from the fact that Austria alone admitted to having lost to the Russians not less than one and a half millions. To the list must be added the prisoners captured by the Americans (48,000 in number), and by the Turks, Bulgarians and the other lesser belligerents. Of this vast host only about 200,000 (probably not much more than 2%) were British, and about 185,000 of these were in the hands of Germany.

When it is further remembered that sometimes in the course of a single operation tens of thousands of men, many of them wounded, were added to the number captured earlier, it will be understood how great was the strain placed on the captors' resources in the matter of transport, care and feeding. Moreover, prisoners were taken in almost every part of the globe in every kind of climate, and in conditions in which the means of supply and transport varied from being comparatively complete to being almost non-existent. Even if all the belligerent Governments had been actuated by the most earnest desire to apply strictly the provisions of the Hague Convention it was inevitable that there should be much suffering and, owing to the difficulty of effective supervision, cases of cruelty and ill-treatment at the hands of individuals.

It must be recognized that, speaking generally, the administrative problems in relation to the treatment of prisoners were not so serious in Great Britain as in most of the belligerent States, but it is satisfactory to be able to record that they were humanely and for the most part satisfactorily solved as they

arose. It is on the other hand unfortunately true that, quite apart from the misery inseparable from prolonged confinement, numbers of British prisoners underwent gratuitous and grievous suffering, especially in territory merely occupied by the enemy and at some of the working camps in Germany, in Bulgaria and in Turkey.

While something is said below with regard to the treatment of prisoners by the Bulgarians and Turks, it is impossible here to attempt to deal with the whole area of hostilities and with the multitude of questions relating to prisoners which arose between the belligerents. This article, therefore, will deal chiefly with the lot of prisoners in Great Britain and Germany, and the application of the Hague regulations in those countries.

Though discussions arose as to the position of such persons as reservists and officers of merchant ships, prisoners of war may be divided into two main classes: (1) Civilian, (2) Combatant.

(1). *Civilian*.—It is quite certain that the framers of the Hague Convention had not in view the treatment of persons other than combatants, but such large numbers of civilians were interned during the war that the arrangements made for them must shortly be considered.

The internment of civilians in both Great Britain and in Germany was, as a system, possibly due to two accidental but different causes. In Great Britain it arose first from the widespread belief, justified probably only in a relatively small number of cases, that the German civilian population in England were either spies in the service of the German Government or an advance guard of a German army of occupation. After this feeling had died down, and release from internment had become general, the system had again to be resorted to after the sinking of the "Lusitania," largely in deference to wide-spread indignation at that outrage and for the protection of the Germans themselves. Even then, however, internment was not general. Every enemy alien had a right to have his case dealt with by an advisory committee, of which Mr. Justice Sankey was chairman and Lord Justice Younger was a member, and by this committee many exemptions were granted.

In Germany, on the other hand, the internment of civilians—ultimately much more indiscriminate than in the United Kingdom—resulted from popular indignation in Germany at the entry of Great Britain into the war.

Thus it was that in both countries—in England by end of Oct. 1914 and in Germany by Nov. 1914—nearly every male enemy national of military age was interned, and the system, as applied to civilians, became established in both countries, although its working in Great Britain was later modified in the manner referred to above.

Accommodation.—The accommodation in both countries was bad in the beginning. In Great Britain some prisoners were at first placed on board ships, but this was found to be unsatisfactory for many reasons. Considerable numbers of aliens were sent to the Newbury race-course, where they lived in loose boxes without any beds and without any adequate sanitary or cooking arrangements; as numbers increased tents were added and various improvements made, but the place was never satisfactory, and it was closed soon after the weather broke in the autumn. It is only mentioned because it seems more than probable that, characteristically enough, Ruhleben (itself a race-course) was selected by the Germans for the internment of British civilians as a reply to Newbury. The problem of finding adequate accommodation was difficult in England where there were eventually some 20,000 Germans interned out of a considerably larger number not interfered with. In Germany the difficulty must have been even greater, as in addition to two and a half million combatants there were nearly 112,000 civilian internees of different nationalities to be provided for; of these only between 5,000 and 6,000 were British.¹

¹ There were in addition to German civilians interned in England a comparatively small number of internees of other nationalities and nearly 20,000 more in other parts of the Empire. The whole of the prisoners in German hands were of course confined in Germany or the occupied districts.

* These figures indicate the volume and page number of the previous article.

After the early unsatisfactory camps in England were closed, civilians were confined in large institutions of different kinds, but eventually far the largest number was placed in the Isle of Man, where there was created at Knockaloe a huge camp containing at last some 23,000 prisoners. There were also two "privilege camps" at Douglas and Wakefield, where those possessed of means could, upon payment, secure a certain amount of privacy and comfort, and employ as their servants other prisoners desirous of earning a little money. There was also Islington Workhouse, perhaps the best place of all, where enemy civilians with British-born wives, or some other claim to consideration, were interned.

In Germany the lot of those who were first arrested was worse than in England. They were cast into the ordinary prisons and treated like convicted criminals. After no long time, however, most of them were transferred to Ruhleben, which, with the exception of Schloss Celle, where a certain number of elderly civilians, whose status was somewhat uncertain, were placed, became the place of confinement for all British civilians.

Ruhleben was a race-course near Berlin, with stables, grandstand and all the usual appurtenances of a race-course. The prisoners were housed in the loose boxes and attics without at first any beds, though eventually ships' berths were fitted, six to a box. As the numbers grew, huts were added. The washing and sanitary arrangements, at first rudimentary only, were never satisfactory. No arrangements were made by the Germans for the housing of the prisoners according to their vocational or social affinities—a real boon in the case of civilians. They were allowed, however, ultimately to some extent to sort themselves.

Management.—At first in both countries the camps were conducted on military lines, but eventually the interned persons were left to manage the internal affairs of the camps very much by themselves. A camp captain was elected by them, and captains of huts or other divisions. The camp captain was the official medium of communication with the authorities.

Work and Recreation.—It was recognized in both countries that civilians might not be forced to do any work beyond what was necessary for the orderliness of the camp. This was a doubtful privilege, and the prisoners' want of occupation led to difficulties in maintaining discipline. In the latter stages of the war, at all events in England, a small proportion of prisoners volunteered to work in order to escape the ennui of camp life, and for some 1,500 out of the whole number, useful work was found, mainly in agriculture. No British civilians did any work outside the camps in Germany.

But much was done by the prisoners themselves. Workshops were organized and equipped with the assistance of the Y.M.C.A. (British and American), and other similar organizations. The difficulty in England was to find a market for the produce of the workshops, owing to the objections raised to the prisoners competing with British workmen. This was overcome by sending the articles manufactured to neutral countries.

Besides this form of manual occupation, classes were formed and lectures delivered, and students were enabled to continue their studies so far as their circumstances permitted, and a small number were employed in administrative work.

Medical Care.—Provision was made in England for the civilian prisoners by small hospitals in each place of internment, for the treatment of minor and urgent cases, while some who had been residents in Great Britain before the war were treated in outside institutions.

At Ruhleben a lazaret to which any prisoners could go was established at the Emigrants' Railway Station, close to the camp. The place had previously been used by a low class, and was filthy. The sanitation was bad, and the accommodation of the roughest description, while the attention given to the patients was, to say the least, perfunctory; a doctor came once a day, and there were no nurses or orderlies. After the first disorganization was remedied, there was what was called the Revier Barrack, with a waiting and consultation room, in which the doctor examined those requiring advice. The place had accommodation for emergency cases and those suffering from

accidents, and persons were kept under observation till it was decided what should be done with them. From here patients were drafted either to the lazaret above mentioned, or to Dr. Weiler's Sanatorium outside but near the camp, established at the suggestion of the American ambassador for the better treatment of the prisoners, in return for a substantial payment made either by the British Government, or by the patients themselves.

Besides these there was the Schonungs Barrack, a place for convalescents and the ailing. Though the building was provided by the German Government, the place owed its existence and all its amenities to the self-denying labours of Mr. Lambert, himself a British prisoner. It proved a real home of rest for those who were not ill enough to require hospital treatment.

One great defect in the arrangements made for the sick prisoners here was that the German Government, as in the camps where combatant prisoners were confined, provided no diet suitable for them. The ration was the same as for men in good health. A proper diet was provided in Dr. Weiler's Sanatorium in return for the substantial payment made by or on behalf of the patients, and in the Schonungs Barrack by Mr. Lambert with the assistance of friends in England.

Lastly, one further fact should be mentioned. In a few exceptional cases persons were allowed to proceed to places far removed from Berlin to complete "cures" which had been interrupted by the outbreak of war.

The position with regard to the care of sick civilian prisoners may be summed up as follows: The German Government provided some, but inadequate, accommodation for the very poor, and did not put any great obstacles in the way of prisoners who could themselves afford, or for whom the British Government or others were willing, to pay for better treatment.

(2). **Combatant Prisoners.**—In considering the application of the Hague Convention to the combatant prisoners, it is impossible to deal with all the subjects mentioned in it. It is proposed to deal at length only with the principal matters, viz. accommodation, food, the application of the military law of the captors, and after touching on a few less important subjects, to consider how the great general principle enunciated in Article 4, that prisoners must be "humanely treated," was acted on.

Accommodation.—German officers in Great Britain were interned in large country houses and public institutions adapted for the purpose, to which, as necessity arose, additions were made, usually in the form of wooden huts. The necessary furniture and everything reasonably required for messing, as well as fuel and light, was provided free of charge. In Germany, however, the housing was in many cases bad and unsuitable. British officers were confined in the casemates of fortresses, as at Ingolstadt; in the men's barracks, as at Crefeld; in disused factories as at Halle, or in huts which had been previously occupied by the rank and file of other nations, as at Holzminden. The best accommodation was in some of the hotels, as at Augustabad, where, until the place became crowded, conditions were comfortable. The British prisoners had to provide, at their own expense, cutlery and everything required for the table, as well as fuel and light, which last caused considerable hardship in winter, for some of the camps were established in summer resorts slightly constructed and at a high altitude.

The actual position of the German places of confinement was undoubtedly chosen in some cases with ulterior objects in view. Thus, the quarters provided right in the middle of the Badische Anilin und Soda Fabrik at Ludwigshafen, and in the centre of Karlsruhe, were undoubtedly chosen in the hopes of warding off air attacks on those places or for the purpose of involving nationals of the raiders in the results.

The men's camps fall into two classes—the large main camps and the working camps.

In both countries the arrangements in the main camps were similar. The camps consisted of groups of huts, either attached to some barracks or similar place, or quite independent, with the necessary cook-houses, baths, latrines and administrative block, all surrounded by a barbed wire fence. There were frequent and justifiable complaints of overcrowding in the German

PRISONERS OF WAR

camps. At Wittenberg, for instance, there was, when the camp was full, a population of from 15,000 to 17,000 on an area of about 10 acres. There was usually a building set apart for religious services and recreation in the form of concerts and theatrical performances. The sleeping accommodation consisted of bunks arranged in two or sometimes three tiers. The camps were divided by barbed wire into compounds containing about 3,200 prisoners—camps within a camp.

Working Camps.—The housing of the prisoners sent out to work is more difficult to deal with comprehensively, for it depended so much on the locality and nature of the work, quite apart from the goodwill or otherwise of the employer. According to the German regulations, there ought to have been five cubic metres of internal capacity for each prisoner of war. This regulation was by no means always observed. The accommodation provided in Germany varied from a single very-well-lit and ventilated bedroom in a farm to crowded filthy quarters in verminous draughty buildings in mines, quarries and brickyards. In the larger working camps, buildings were sometimes erected for the express purpose of housing the prisoners, and, though not infrequently overcrowded, were generally suited for this purpose. These buildings were sometimes of brick, more usually of wood, set up somewhat above the ground level. In E. Prussia, however, and in a few other places, a construction common in the neighbourhood was used. The huts were sunk into the ground and were in fact something like large lined dugouts roofed over. They were not satisfactory for considerable numbers, but had the advantage that they were in that bleak district warmer in winter than if they had been erected wholly above ground. In other cases, the prisoners lived in the quarters which at many mines and large industrial works the employers provided for their own bachelor workmen. Such quarters were usually satisfactory. The situation of these quarters, of course, depended on the conditions existing locally, and the nature of the work. In mines they were usually in the mine compound, in some places they were situated at a distance from the actual place of working, and thus was added to the day's labour a walk of occasionally as much as 5 km. each way—a serious addition if the work was severe. But in the majority of cases there were no workmen's quarters, and it was impracticable to build barracks for only a few prisoners. Accommodation was then provided in village recreation halls, inns, theatres and similar places. They were not well adapted for the purpose, but where a little goodwill was shewn on both sides, were often made reasonably comfortable.

In a few cases, at Kiel and elsewhere in that neighbourhood, the prisoners lived on board ship where the accommodation, according to the neutral reports, seems to have been satisfactory.

In the places dealt with above, good provision was usually made for bathing, personal washing and laundry; in many mines and industrial works the men were able to get a hot shower-bath daily. In some places, on the other hand, the quarters provided were disgusting. To take two instances out of many which might be given. At Fangslause, attached to Döberitz, where the men were engaged in refuse sorting, the barracks consisted of a wooden building divided into two rooms, which were very dirty, in a verminous condition, and overrun with rats and mice. There were no arrangements for bathing or washing; the only opportunity the men had for washing being afforded by a canal near by. At another place, a coalyard, the men were housed in an archway under one of the main lines running into Berlin, and bathing arrangements were nil.

In Great Britain, prisoners of war sent to work were either housed by the military authorities or, in some cases, when engaged in agriculture, by the employer, who was bound to supply housing accommodation, straw for filling palliasses, cooking utensils, crockery, facilities for washing and artificial light. As in Germany, it was not always found possible in England to house prisoners near their work. Any time required to reach and return from their work in excess of one hour was deducted from the hours of labour. One rest day a week was allowed in both countries.

Work.—The construction placed during the World War by the belligerents upon Article 6, which enables the captors to employ the labour of prisoners of war and to authorize them to work for the public service or private persons, probably caused more ill-feeling than any other cause, for the result was to reduce hundreds of thousands of men temporarily to virtual, if not nominal, slavery. In the war of 1870-1 the Germans took some 400,000 French as prisoners. They were permitted, but in no way forced, to work in factories and elsewhere. During the World War, with many exceptions, it is true, practically all able-bodied prisoners, except officers and non-commissioned officers, were ultimately forced to work.

Early in 1915 the British prisoners in German hands were invited to volunteer for work outside the main camps. They refused almost to a man. Then by degrees pressure was applied, and soon men who refused were punished for their refusal, and, eventually, as mentioned below, a formal pronouncement on the subject was made by the German Military Courts.

Meanwhile, a question arose as to the employment of non-commissioned officers. As early as February 1915, the German Government suggested certain privileges for superior non-commissioned officers, and eventually an agreement was come to, that non-commissioned officers should not be compelled to work, except as superintendents, unless they volunteered to do so. A camp was formed for non-commissioned officers at Grossenweder Moor, in the notorious X. Army Corps district, and steps were taken to obtain volunteers for work by withdrawing all privileges and forcing the men to march on parade for nine hours a day. The men did not volunteer and eventually the conditions were improved.

The question of the nature of the work which could be properly demanded of prisoners of war was early found to be a difficult one. In a war of nations such as the World War every able-bodied man replaced by a prisoner is a potential soldier, and, in these circumstances, any work in the enemy country might be said to be "indirectly connected with the operations of war," especially in cases in which the prisoner was engaged in any step in the manufacture or transport of any one of the multitude of articles necessary for an army in the field.

The position first taken up by the German authorities was that so long as prisoners did not actually handle the finished product—arms, ammunition and such like—there was no infraction of the rules of international law. This, however, did not really cover the whole ground, and the matter was eventually formally considered by the German Military Courts, and the following principles were laid down:—

- (1) The work on which a prisoner of war may be employed can only be judged on the merits of each particular case.
- (2) It is illegal to employ prisoners of war in the manufacture of munitions intended for use against their native country or its allies.
- (3) They may be employed in agricultural or forestry work, as well as on military property, e.g. the improvement of parade and drill-grounds and of rifle ranges.
- (4) They may be employed on preparation work, e.g. the transport of coke or of ores for the manufacture of shells, because there is no direct connexion between such work and military operations.
- (5) They can only claim exemption from such work as stands in direct relation to military operations in the area of hostilities.

These principles were accepted by the British War Office and the commanders-in-chief of the British armies, and seem on the whole to have been fairly acted on by the German authorities except behind the lines on the eastern and western fronts, though in some cases individual commandants attempted to force men to take part in the actual manufacture of such things as shells, parts of fuzes and the like.

There seem to have been a large number of them employed in labouring work, handling the actual material for guns, shells, etc., in places where munitions were made, and some cases in which they had to take an active part in the manufacture of the finished article certainly did occur. At Krupp's Germania wharf at Kiel, prisoners were employed in riveting ships, including the outsides of submarines, while at Mannheim a number of British were made to work in the manufacture of sulphuric acid in the middle of a large munition factory.

The authorities naturally reserved to themselves the right to say what work the prisoners could be forced to do, but, at all events in the early years of the war, they promised to give to the prisoners certificates that they had been forced to do the work to which they objected in order to protect them against proceedings in their own country. The promise seems to have been very seldom kept.

Setting aside work directly or indirectly connected with the operations of war there seems to have been no kind of work which prisoners were not called on to perform. They were employed in every kind of manual labour, including work in mines, from skilled engineering to scavenging. This last seems to transgress the principles laid down in the German War Book, that "these tasks" (to which prisoners can be put) "should not be prejudicial to health nor in any way dishonourable."

In Berlin prisoners were sent to work in a slaughterhouse; at three places they were obliged to do scavenging in the public streets, while at two places at Kiel, and at four places near Berlin they had to collect and sort the rubbish of the town. The visitor of the protecting Power says in his report of one of the places at Kiel where only British prisoners were employed, "the work the prisoners are called on to perform is of a particularly revolting character."

In Great Britain, the principles above stated having been accepted, prisoners were employed in accordance with them, but none were employed in mines, nor were such degrading tasks as scavenging and refuse-sorting imposed on them. A large number were employed in France in various capacities not directly connected with the operations of war, and, after the Armistice, in general salvage work.

The organization of the working camps was much the same in both countries. Each working camp was connected with a main camp, which was the centre for all administrative purposes and upon its books the prisoners were borne.

In Germany the working camps were divided into three classes:—(a) those which the representative of the protecting Power might visit freely and see the men at their work and in their quarters; (b) those in which he might see them in their quarters but not at work; and (c) those in which he was admitted neither to the work nor to the quarters but was allowed to see one or more prisoners outside. It has been suggested that this classification was due to the influence of some of the great industrial magnates who objected to their works being visited by outsiders, but, however this may be, the third class was a very small one, and the prohibition with regard to the second and third classes does not appear to have been very strictly enforced.

Pay.—The provisions of the Hague Convention with regard to pay are too vague to be of any real value.

In the II. Army Corps district the German regulations, which may be taken as typical, seemed to contemplate a payment by the employer of the customary local wages, of which the military administrative department took three-quarters for board, lodging, guarding, etc., and the prisoner was credited with one quarter, which he received in token money. In practice, a prisoner working on the land generally himself received 30 pf. a day, in mines from 75 to 90 pf., and in industrial works from 50 pf. to even several marks a day. In some cases a premium was paid to prisoners who did more than the minimum.

Prisoners of war in British hands, when employed by the Government, received the same rate of pay as that given to British soldiers as working pay. When employed by private persons or corporations the employer in England was obliged to pay the full current rate of wages to the Government by whom the prisoner was paid. Piece-work or task-work was adopted where possible and extra pay given where the task was exceeded. The rates were so adjusted that a man of moderate industry could earn the equivalent of time-work earnings, and a very industrious man could earn more. Time-work was paid at rates which ranged according to circumstances from 1s. 4d. to 8d. a day. These sums were credited to the prisoner, but power was reserved to the commandant to decide the amount actually issued to the prisoner.

Food.—Article 7 imposes on the captor State the duty of maintaining its prisoners, and provides for their being treated as regards rations, quarters and clothing on the same footing as its own troops. This article is difficult to understand; it is not clear whether prisoners are to have the same rations as soldiers in the field or at home; or whether they are to be placed in barracks with the same space and conveniences as the captor's soldiers. How this last matter was actually dealt with has been already explained. Whatever may be the true construction of the article, none of the belligerents observed the letter of it with regard to food. Difficulties arose, not merely from the steadily decreasing supplies, owing to the submarine war on one side and the blockade of Germany on the other, but also from the difference in the kind of food appreciated by the subjects of the two countries. At a time when the Germans interned in England were receiving the full peace-time rations of the British soldier, they were complaining of the insufficiency and unpalatable nature of the food. On the other hand, the British prisoners—even when supplies were sufficient in Germany—complained of the brown or black bread, and of the soup, which is liked by the continental working man.

In England, after a short time, no rations were issued to officers. Canteens were established, and subject to regulations for the prevention of undue luxury, the German officers could provide such food as they wished, which was prepared for them by cooks of their own nationality.

In Germany it was different. Rations were issued, though not always partaken of. The British officers, at all events after the war had continued for some time, lived almost entirely on supplies obtained from home. The rations in Germany were issued according to a scale based upon a scientific analysis of the composition of the food given, which showed a daily average in grammes of albumen, fat and carbo-hydrates, and the number of calories. These, as determined by the Kriegsministerium for the last week in Sept. 1916 at Parchim Camp, averaged daily 75.6, 24.5, 368.4 and 2,010.4 respectively.

It perhaps throws some light on the sufficiency of this ration that in July 1918, nearly two years later, it was agreed between the representatives of Great Britain and Germany, who met at The Hague, that the combatant prisoners of war should receive as far as possible the same allowance of rationed articles of food as the civil population, and that in no case should the daily caloric value fall below 2,000 calories for non-workers, 2,500 for ordinary workers, and 2,800 for heavy workers.

It may be doubted, however, whether at any time in German camps the prisoners received even these moderate amounts of food; and as the supplies became more difficult to obtain, they probably received considerably less, even in the working camps. Even if they did, such things as fish roe, soya flour, soya oil, buckwheat and "blutwurst" do not appeal to a British soldier, however admirable they may be from a scientific point of view as articles of food, especially when they are all boiled together and given in the form of soup.

In England the scales were not drawn up in exactly the same way. If we take the principal articles of food, up to the middle of 1916 the German prisoners received a daily ration of 1½ lb. of bread, 8 oz. of fresh or frozen meat or 4 oz. of preserved, 2 oz. of cheese and 1 oz. of margarine. By Dec. 1917, the ration had been much reduced. The bread ration was 13 oz., for 4 oz. of which broken biscuit was substituted when obtainable. Meat was given on three days a week only, but a ration of 20 oz. of herring was added on two days. The 2 oz. of cheese and 1 oz. of margarine were given till Oct. 1918, when both were reduced. In the case of non-workers, the bread in Oct. 1918 was reduced by a quarter of a pound, the cheese omitted, and the margarine further reduced. In England, as in Germany, the prisoners had to share in the privations of the civilian population.

In both countries the rations were supplemented by parcels of food which were sent to the prisoners. At first they were sent from England by individuals and associations, but before long great abuses arose. Some British prisoners received large numbers of parcels, not infrequently far beyond any possible require-

ments. Others received nothing, and there can be no doubt that in not a few cases gross fraud was practised on sympathetic persons. Early in 1915 the Prisoners of War Help Committee was established in London. It tried to coördinate the work of the different associations and individuals, but failed as it had no powers, and was dissolved in Sept. 1916, when the Central Prisoners of War Committee of the British Red Cross and Order of St. John was officially established and without its authorization no individual or body could send a parcel to a prisoner.

Amongst its functions were (1) to authorize committees, associations and approved shops to pack and despatch parcels to prisoners of war, (2) to control and coördinate the work of all such committees, associations and shops, and (3) to act as a care committee for all prisoners who for any reason were without a care committee, for all civilian prisoners, and, after Oct. 1917, for all officer prisoners.

Under the presidency of Sir Starr Jameson, Bart., and, after his death, of the Earl of Sandwich, the committee of which Sir P. D. Agnew was vice-chairman and managing-director, not only organized the whole of the despatch of parcels of food and other things to the prisoners of war by 181 care committees, 81 local associations and 67 shops, but packed and despatched parcels to individual officers and men, numbering, at the date of the Armistice, no less than 47,500. Three parcels of 11 lb. weight were sent each fortnight to every prisoner and contained, together with 13 lb. of bread sent once a fortnight from Copenhagen or Berne, sufficient, without other food, to maintain a man doing reasonably hard work. Officers did not come under the scheme till the autumn of 1917.

At first the scheme was very unpopular, because it interfered with the power of individuals to send what they liked to their friends, and in April 1917, a Joint Committee of both Houses of Parliament was appointed to enquire into it. The report was published in June of that year, and while paying a high tribute of praise to the work accomplished made certain suggestions which did much to allay the discontent, as they provided for the introduction of the personal touch into the parcels. In its main features the scheme continued till the end of the war.

Besides the despatch of parcels to individuals the Committee sent food, either in bulk or in the form of emergency parcels, to the larger camps in Germany, for newly captured prisoners.

Though it is obvious that the despatch of parcels of food on the great scale indicated above relieved the German Government of a very great responsibility, yet it must be recognized that credit is due to the German nation for the fact that all but a small percentage reached the addressees to which they were sent, notwithstanding that they contained articles unobtainable in Germany, except by the very rich.

Though it is true that the parcels arrived, it is also true that in some camps the German commandants as a punishment delayed or prohibited for some days or even weeks their issue to the addressees, and that there were complaints as to the way in which the censoring of the contents of the parcels, necessary of course to prevent the introduction of prohibited articles, was carried out. Latterly, however, in all good camps the parcels were opened in the presence of the addressee, and the tinned food was stored and not opened till it was required.

Owing to the increasing shortage of food in Germany, and to the fact that the rations in England for a long time were maintained at a reasonable level, the number of parcels sent to German prisoners was far smaller than that sent to British prisoners. At first a considerable amount of food was sent into the German prisoners' camps in England from their relations and friends residing in Great Britain, but when the shortage became acute it became necessary to prohibit this practice.

The Hague Convention also requires the captor to treat his prisoners as regards clothing on the same footing as his own soldiers. The German Government claimed that it strictly observed this article and forbade the sending of clothing by the British Government. The article was not observed at all in some German camps, and great trouble was caused by the claim, in at all events some army corps, that boots were part of a sol-

dier's military equipment, and that the captors were entitled to take them. The clothing in any case supplied by the Germans was quite insufficient, and arrangements were made by which an adequate supply was despatched according to a regular scale. Some of it went astray and some was stolen, although a good proportion reached the addressees. In England clothing was issued when necessary to enemy prisoners, other than officers, on a regular scale, which provided for them having a sufficient change of clothing, while in both countries officers made their own arrangements for the supply of the necessary clothing.

Application of the Military Law of the Captors.—Article 8 enacts that prisoners of war are subject to the laws, regulations and orders in force in the army of the captor State, a provision which gave rise to a good deal of trouble, owing, in England, to the difficulty of carrying it out strictly—while in some cases, as in Bulgaria, punishments were allowed—such as flogging—for ordinary breaches of discipline—which were quite alien to British ideas of what is permissible.

The German military law is in general far more severe than the British, and there is this further great difference, that in Germany officers as well as men may be summarily sent to cells or awarded other severe punishments for trivial offences, while in the United Kingdom, strictly, any offender above the rank of private should have been tried by court-martial, a provision amended during the war by the substitution of military courts.

In another respect the German code is more severe in that all sentences of arrest involved solitary confinement, while one of close arrest, which was limited to four weeks, meant that the prisoner was confined in a dark cell, with a plank bed and bread and water diet, though these aggravations of the punishment were omitted on the fourth, eighth and subsequently every third day, the prisoner receiving the ordinary camp diet on these days.

One punishment officially termed "field punishment," but more generally known in England as the "post punishment," caused a great outcry in that country and much resentment among British prisoners in Germany. It is provided in the German *Manual of Military Law* that the punishment is to be inflicted in a manner not detrimental to the health of the prisoner, who is to be kept in an upright position with the back turned to a wall or a tree in such a manner that the prisoner can neither sit nor lie down. These last words were construed to mean tying the prisoner to a post; sometimes his feet were placed on a brick which was removed after he was securely tied, and sometimes his hands were secured above his head. Apart, at all events, from these aggravations, this punishment was in strict accordance with the military law of the captors; indeed it corresponds to the field punishment No. 1 authorized by the British military law and described in the rules for field punishment for offences committed on active service made under Sec. 44 of the Army Act. These rules authorize the keeping of the offender in fetters or handcuffs or both, and when so kept he may be attached by straps or ropes for a period or periods not exceeding two hours in any one day to a fixed object during not more than three out of four consecutive days nor more than twenty-one days in all.

In Germany all prisoners are liable to be treated as "in the field," i.e. on active service.

In one respect, viz. the punishments for attempted escape, the German military law was less severe than the British, the greater severity of the latter having apparently arisen from a misunderstanding of the expression "peines disciplinaires" in the second paragraph of the 8th Article of the Hague Convention. This seems to have been understood on the Continent as a punishment which could be awarded summarily: that is, arrest, open, medium or close, for a period not exceeding six weeks. In Great Britain the punishment was limited to 12 months' imprisonment; in Germany it was far less for the simple offence, though it was frequently added to by the addition of charges for damaging Government property, and the like. The matter came under discussion between the British and German Delegates at The Hague in 1917 and 1918, and an agreement was arrived at by which the punishment for a simple attempt to escape was to be limited to fourteen days, or if accompanied with offences relating

to the appropriation, possession of or injury to property to two months' military confinement.

In addition to the summary punishments, there were, of course, in both countries the punishment of death and imprisonment, which could only be inflicted by court-martial. In some cases the German code lays down minimum punishments of great severity, and in many of those cases, in which the infliction of very severe punishments properly raised a great outcry in England, the German court-martial had no option but to pass them. The British military law on the other hand has only one offence—murder—for which there is a fixed punishment; for others it is "such less punishment as is in the Act mentioned."

In one respect the prisoners of both countries never were satisfied. Neither understood or appreciated the procedure of the other. The British never understood the long delays, sometimes it is to be feared deliberate, which occurred in bringing them to trial for alleged offences, and during which they were kept under arrest, nor, owing to their ignorance of the German military code, could they understand the very severe sentences necessarily passed by courts-martial (which seem usually to have been conducted with fairness), nor the right of the prosecutor to appeal against a sentence which he considered to be inadequate.

On the other hand, the Germans never appreciated the British procedure, nor could they understand the absence of any right of formal appeal from a sentence, for which ample provision is made in Germany, even against the award of a disciplinary punishment, a right which, oddly enough, by Sec. 52 of the Regulations relating to it, the accused shared with the prosecutor "only when the sentence has been carried out."

Parole.—Articles 10, 11 and 12 deal with the subject of parole. In the World War no combatant prisoners, with one exception, were allowed to leave Germany or Great Britain on parole, or to reside outside the camps. The only cases in which questions arose were with regard to the temporary parole given when officers left their camps for a walk, and the parole given by those who were interned in neutral countries. According to the custom of the British Army no officer ought to give his parole, it being his duty to escape and rejoin his unit if he can, nor can anyone below the rank of officer give a parole. In both countries, however, officers were eventually allowed to go out for a walk in parties accompanied by an officer, each giving in writing a temporary written parole that he would not attempt to escape, nor during the walk make arrangements to escape, nor do anything to the prejudice of the captor State. The parole was given on leaving the camp and returned on reentry.

The case of those interned in neutral countries was different. The British officers of the Royal Naval Division interned in Holland after the fall of Antwerp were permitted to choose their own residence in Groningen on parole, the men being interned close by. This privilege was withdrawn for a time, and the officers were interned in a fortress, but it was restored later.

As time went on, the Netherlands Government permitted officers to return to England and Germany on parole, on proof of the serious illness of a near relative, a concession which was afterwards extended so that regular periods of leave were enjoyed by both officers and men, the former giving a formal parole and the latter a promise to return on the expiration of their leave, while the British Government gave its assurance that the men would not be employed on any work to do with war, and would return at the end of their leave. Similarly, the Danish and Norwegian Governments granted leave to British and German combatants interned in their countries.

No parole seems to have been taken from those officers who were interned in Switzerland or Holland under the agreements made in 1917 and 1918 with the German Government.

Relief Societies.—Article 15 deals with societies for the relief of prisoners. An immense amount of valuable work, impossible here to particularize, was done by such societies. The American branch of the Y.M.C.A. especially did much for the prisoners in England and Germany, being permitted to work on the following conditions, substantially the same in both countries.

A building or tent might be erected in the camp with the consent of the general officer in command of the district or army corps, but nothing might be sold in it nor could any one be employed there other than a prisoner. A member of the association might visit the camp once a week for a definite time. He might hold services, provide materials for games, entertainments and employment, arrange instructional courses, provide books (subject to censorship) and writing materials other than writing paper and envelopes. Nothing might be given to or received by a prisoner without the commandant's consent.

Recreation.—No express provision is contained in the Hague Convention relating to the occupation of prisoners in their leisure time, but much of the good work done by the societies had to do with the recreation and education of prisoners. In both countries, and in nearly all camps, provision was eventually made for sufficient space for recreation and exercise, but this was not the case at first. At Halle, for instance, a German camp for officers, established in a disused factory, the only place for exercise was the space enclosed by the three buildings, in which some 500 officers lived. It measured about 100 yards by 50, and in winter was a morass of water and mud; in summer deep in dust. In some of the men's camps the space was very confined, and organized games of any kind were impossible. But later things improved, and in most provision, sometimes at the prisoners' expense, was made for sufficient room for tennis, football and other games.

In England, facilities were provided by the War Office. To take two typical instances, it may be said that at Donnington Hall for German officers, there was a considerable space in front of the house, and at Dorchester, for men, there was a large field where any games could be played.

As time went on, walks outside the camp were permitted for officers on their giving a temporary parole, and in Germany, in some of the larger working camps, the men were allowed out for walks on Sunday.

With regard to educational facilities, in England both officers and men made their own arrangements, as they did in Germany, with the full concurrence of the authorities. At Münster, for instance, the general officer commanding excused all students from work, and much was done by some of the prisoners in the organization of classes and lectures. The neutral organizations, such as the American and Danish Y.M.C.A.'s, also did a great deal in this direction, as did certain of the German civilians in the neighbourhood of the great camp at Göttingen. Professor Stange and some of his colleagues interested themselves in the prisoners and organized the educational work in the camp, and he himself had an office there where he was accessible to prisoners, and assisted them with his advice on educational matters. He used even to obtain the requisites for games through the Red Cross in Switzerland. Unfortunately for them, all the British prisoners were ultimately removed from Göttingen, which had become something of a model camp.

Some of the larger employers were also very considerate in this respect, providing recreation halls and fields for playing games, and even musical instruments. At Mulheim the Dutch visitor found the employers had paid the expenses of the prisoners' Christmas festivities.

Letters.—Article 16 was observed by both countries, except that at one time in some of the camps in Germany customs duties were charged on the contents of parcels, but this seems to have been due to some misapprehension, and was soon abandoned. Prisoners were as a rule allowed to write two letters a month and a postcard every week, and, in addition, a postcard in the prescribed form acknowledging the receipt of a parcel. But later in the war a "first capture postcard" was introduced, by which on a printed form a prisoner was allowed to notify to his relatives his capture, his state of health and his address.

Pay.—Article 17 provides for officers receiving the same rate of pay as officers of the corresponding rank in the army of the captors. This provision was not observed by the German Government, who paid subalterns 60 marks a month and other ranks rather more. Accordingly, the British Government

declined to carry out the terms of the article and paid the German subalterns 4s. a day and other ranks 4s. 6d., naval officers being paid according to their relative rank. Out of this an officer was required to pay for his food, laundry and clothing, a deduction being made if he was in hospital (where, of course, he was provided with everything necessary). By an arrangement made later the German Government was allowed to make a small addition to these daily rates of pay. Medical officers employed in the care of sick and wounded prisoners of their own nationality received the full pay of medical officers of corresponding rank in the army of the captors.

Religious Exercises.—Article 18 is designed to secure to prisoners complete liberty in the exercise of their religion, and during the World War no real complaint was made on either side.

In the United Kingdom German pastors who had been resident in the country were allowed to hold services in the camps, but difficulties arose and the permission was withdrawn. Thereupon some pastors elected to be interned, with a view to ministering to the prisoners. Later, however, the permits were issued in a modified form, and English and American clergy and laymen and members of the Danish and Swiss Student Christian Movement were allowed to visit the camps, the necessary funds being provided by the American Branch of the Y.M.C.A. The Roman Catholic prisoners were usually attended by the priest of the district in which the camp was situated and every facility was given to them. Where no German-speaking priest was at hand the Cardinal Archbishop of Westminster charged the German priests of his archdiocese to visit the camps every now and then in order to enable the prisoners to go to confession and to hear a sermon in their mother tongue.

In Germany, at first, the Rev. F. Williams, who had been in charge of the English Church in Berlin, was allowed to visit the different camps and hospitals. But this permission was withdrawn and the prisoners were left to conduct their own services, to which, except at Grossenweder Moor, no objection was raised. A few British chaplains were captured, and did good work until they were repatriated. Great assistance was given also by the American branch of the Y.M.C.A., and by Archdeacon Nies, an American clergyman at Munich, until the United States came into the war.

The German clergy also did what they could for the prisoners in many camps and hospitals. Some of them were spoken of very warmly by the British prisoners.

The needs of the Roman Catholics were more easily met owing to the presence among the French prisoners of many priests who did excellent work, and the Bishop of Paderborn (afterwards Archbishop of Cologne) did much for the prisoners. Moreover, Father Crotty was sent from Rome and was permitted to minister at Limburg and Giessen, partly perhaps because he was an Irishman, and it was hoped his influence might be useful to the Germans.

In the German working camps there was no regular provision for religious services, though Mr. Williams seems to have visited some of the larger places, and in one district a German pastor is said to have travelled around the small camps and ministered to the prisoners. There was a standing order of the Kriegsministerium that, at all events in the country districts, the prisoners should be allowed to attend the local churches. This, though of value to Roman Catholics, was not much use to the Protestants, owing to the difficulties of language.

At Zossen the Germans built a mosque for Mahomedan prisoners, and generally arrangements seem to have been made to avoid hurting religious and caste prejudices.

Medical Treatment.—Up to this point an attempt has been made to show how the provisions of the Hague Convention were applied in Great Britain and Germany. But this Convention does not deal with everything which affects the well-being of prisoners of war. The Geneva Convention of 1906 requires the belligerents to respect and take care of the wounded and sick without distinction of nationality, and leaves them at liberty to agree for the restoration of wounded left on the field, the repatriation of wounded after rendering them fit for removal

or after recovery, and for handing over the sick and wounded to a neutral State to be interned by it till the conclusion of hostilities. What was in fact done must be considered under three heads: the attention given (1) in the regular hospitals, (2) in the main camps and (3) in the working camps.

Hospitals.—In Germany at first there seem to have been inadequate arrangements made for the reception of seriously wounded prisoners, but later well-arranged and well-equipped hospitals were available, the principal being in Berlin, at Cologne and Paderborn, though of course there were a large number elsewhere. As time went on and the pressure on Germany became more and more acute, the supply of medical requisites became deficient, bandages were made of paper, drugs and anaesthetics were less plentiful, but, though naturally British prisoners would fare worse than the wounded Germans, there is no evidence that the former were intentionally deprived of anything necessary for them if there was an adequate supply.

The conduct of the German doctors to the prisoners in the regular hospitals is one of the bright pages in the sad history of the World War, and is worthy of their great profession. Most of the returned British prisoners reported that the doctors were kind and humane, while many of them spoke of them in warmest possible terms and told how the doctor had said that when a prisoner was wounded or ill he no longer looked on him as an enemy, or how, though he hated the English, he did his very best. There were exceptions, who formed a very small minority. The large majority of German doctors worked hard, often with infinite kindness, in the interests of those in their charge, and unreservedly placed such knowledge and skill as they possessed at the disposal of the prisoners.

The nursing in Germany was carried out by orderlies, by trained nurses or by sisterhoods. It seems to have varied very much. In some cases it was good and kind, in some indifferent, and in some rough and bad. But there appears to be no reason to think that in any case it was intentionally less good than circumstances permitted.

Main Camps.—The same satisfactory account of the medical arrangements in the main German camps cannot be given, even after the first disorganization was overcome. There was in each camp a lazaret providing accommodation for a number proportionate to the number for which the camp was designed, but the arrangements were often very incomplete.

There seem to have been a large number of Russian doctors employed in the German camps, while in a few, for short periods, English medical officers were employed—though in all cases a German seems to have been responsible. The nursing was in the main done by prisoner orderlies, many of whom of course were quite untrained, though they seem to have done their best. It is impossible to generalize as to the conduct of the German medical staff in hundreds of camps over a period of four years, but the general impression produced by the evidence is that the staffs were humane and did all they could.

There is reliable evidence that the nature of the food provided in the German camp hospitals, as distinguished from the regular hospitals, where, until supplies became very short, it seems to have been satisfactory, was quite unsuited for invalids. A sick prisoner was a non-worker, and therefore received the ordinary camp ration, less 10 per cent. This was even the case in the typhus camps, where the requisite milk and light food for the fever-stricken patients had to be provided by the British and Allied medical officers themselves.

There seems to have been insufficient care, at all events in the early stages of the war, to prevent the spread of tuberculosis by the segregation from the healthy of those suffering from that disease. Later, however, steps were taken to effect this, and more than one place was established exclusively for tuberculous patients, while the arrangement made for their internment in Switzerland did still more to deal with this evil.

It must not of course be said that this mingling of the sick and healthy was deliberate. It was probably due to want of thought, an excuse which cannot be made for the policy adopted by the German Government of mixing all the Allies together,

although this was bound in the circumstances to lead to an excessive amount of illness. This policy was quite deliberate. Mr. Gerard, the American ambassador to Germany, in 1915 raised the question with the German authorities with regard to officers, and reported: "I was told that this was a political move ordered for the purpose of showing to the French, British, Belgian and Russian officers that they were not natural Allies." The commandant of the Gardelegen camp tried to enforce the observance of this regulation during the height of the typhus epidemic at that camp, but his direct order was deliberately disobeyed by the British doctors, with excellent results.

Though this policy did not produce any ill effects upon the health of the prisoners in the officers' camps in Germany, its results, assisted by the insanitary condition of many of them, were disastrous in the main men's camps. Typhus is endemic in Russia, and the Russian prisoners, herded together with those of other nationalities, spread the disease till in some camps appalling epidemics were produced. At Ohdruf, Langensalza, Zerbst, Wittenberg and Gardelegen the fever raged with great virulence. At Wittenberg the camp was overcrowded and insanitary, the washing arrangements were nothing more than troughs in the open, which, with the supply pipes, were during the hard winter of 1914 frequently frozen. In these circumstances, a serious epidemic broke out in Dec. 1914. As soon as this was recognized, the whole German staff, military and medical, left, and never came inside again till Aug. 1915, by which time all the patients were convalescent. For his services in combating the epidemic Dr. Aschenbach, the German principal medical officer, received the Iron Cross. Many Allied and British medical officers had been improperly detained in Germany after their capture, and were dispatched to take the place of the German doctors, who (it is charitable to believe, in obedience to superior orders) had deserted their charges. In Feb. 1915, six British medical officers were sent to the camp which they found in a state of misery and disorganization. Of the six, three died of the fever, as did several French and Russian doctors. Notwithstanding the fact that there seem to have been ample supplies of medical necessities available, the difficulty of obtaining sufficient drugs and dressings was extreme. There was not even any soap till one of the British doctors obtained a supply at his own expense from England, nor, till April 1915, were beds or bedding for patients requiring hospital treatment improvised in one of the barracks. There were between 700 and 800 British prisoners among at least 15,000 in all, who, incredible as it may seem, were confined in an area not exceeding 10½ acres. Of the British about 300 were attacked by the disease and 60 died.

At Gardelegen the same story was repeated. As soon as it was apparent in February 1915 that something was wrong, captured medical officers were dispatched to Gardelegen, where the conditions were favourable for the propagation of disease. Though there were empty huts in the camp, the commandant refused to allow them to be used, and the prisoners' rooms were very overcrowded, the nationalities, as usual, being all mixed up together. To each company of 1,200 men was allotted for washing one outdoor trough, which was often frozen, and there was a small hut containing at the most thirty showers for 11,000 men. The place was bitterly cold, the heating arrangements entirely inadequate, consequently the huts were kept closed, and the atmosphere therein became foul. Four days after the arrival of the Allied medical officers every German had left the camp, and the commandant, standing outside the barbed wire, informed the medical officers that no person or thing was to pass out, and that they were responsible for the discipline and general internal arrangement of the camp, and for the care of the sick. Dr. Wenzil, the German principal medical officer, left the camp with the rest, but soon afterwards died of typhus. His two successors never came inside the camp. But the third, Dr. Kranski, a civilian, came in March and devoted himself seriously to the welfare of the camp, and, though he took no part in the care of the sick, did much to improve the sanitation, and in that way to aid the medical men in their work. It is unnecessary to go through the whole story of the struggles to obtain

the barest requisites in the way of food, drugs, dressings or furniture. The plague was stayed after four months, during which over 2,000 cases were treated out of 11,000 prisoners, the mortality being about 15% of those attacked. Of the 16 Allied medical officers, 12 took the disease and 3 died, while of 10 French priests, who devoted themselves to the care and tending of the sick, eight were attacked and five succumbed.

The epidemics at Wittenberg and Gardelegen in these circumstances of gratuitous suffering and official callousness made a world-impression never likely to be entirely effaced, but it is only just to add that the German authorities, having learnt their lesson at the cost to others of so much suffering and death, did their best, too late indeed, to remedy the defects, and Gardelegen and Wittenberg eventually became, if not model, at all events fairly satisfactory camps.

German Working Camps.—In mines and large industrial places, there was generally a small sick-bay containing from two or three beds up to perhaps a dozen, in charge of a German Sanitater. There was no resident doctor, but a civilian practitioner called in well-managed camps daily, in others at intervals varying from twice a week to four weeks. In case of accident he was summoned as soon as the *Feldwebel* in charge thought fit. In the smaller camps reliance was placed simply on the local practitioner, which ordinarily was sufficient provision, though in some places, such as the large land reclamation camps in Hanover, the nearest doctor might live at any distance up to 20 kilometres. A prisoner seriously ill or injured was either taken to the hospital at the main camp to which his commando was attached, or sent to the local hospital, military or civil.

The real defect in the medical arrangements in these places was that too much power was left in the hands of the person in charge to decide whether a man reporting sick should see the doctor or not. The regulations in the II. Army Corps district provided that there must be a clinical thermometer in each commando, and the guard was to be instructed in the use of it. No prisoner was to be sent to work who had a temperature above 38° (100.4° Fahrenheit). This seems to have been construed as meaning that the prisoner was to be sent to work unless he could show that temperature. Armed with his thermometer the *Feldwebel* in charge often declined to allow the prisoner to see the doctor. The test was in some cases sufficient, in many it was no test at all, and the results were sometimes fatal.

British Medical Arrangements.—In the United Kingdom the arrangements for the treatment of sick and wounded prisoners did not differ in essentials from those made in Germany. At first there were no special hospitals for them, but in Sept. 1915 a large hospital was opened at Dartford. This accommodation, however, soon became insufficient, and at the time of the Armistice there were seven hospitals entirely set apart for prisoners. In addition to these large hospitals there was a hospital with beds to the number of about 2% of the prisoners, for the treatment of minor and urgent cases; while in the working camps the services of the local practitioner were given as required. In exceptional cases prisoners requiring special treatment were sent to an ordinary military or civil hospital.

Repatriation.—Closely allied with the matter of medical treatment is the question of repatriation and internment in a neutral country. As early as Jan. 1915, an agreement for repatriation of incapacitated officers was made. There was at first no agreement as to the degree of incapacity sufficient to entitle an officer to repatriation, but in August of that year an agreement was arrived at, which was slightly amended in October. It included 13 injuries or complaints entitling a person to be repatriated, which may be summed up as being such that the person was permanently, or for a calculable period, unfit for military service in the army, or in the case of an officer or non-commissioned officer, from service in training or office work.

But besides this direct repatriation of totally incapacitated persons, many prisoners were sent to Switzerland or Holland.

In the spring of 1916 an agreement was made with the German and Swiss Governments by which prisoners whose disabilities fell within an agreed schedule but were not sufficient to

justify direct repatriation should be transferred to Swiss custody. They were selected by mixed travelling boards composed of Swiss medical men and medical officers of the captor State, those selected being afterwards examined by a Control Board, whose decision was final. After the Conference at The Hague in 1917, these travelling boards were abolished, and the first selection made by the camp medical officer, an arrangement subsequently modified at the meeting of 1918.

The guiding principles for internment in Switzerland were stated in 1917 as follows:—

"The following shall be interned:—(1) Sick and wounded whose recovery may be anticipated within a year, and whose cure will be more speedily and surely brought about by the facilities obtainable in Switzerland than by a prolongation of imprisonment. (2) Prisoners of war whose health in the opinion of the medical authorities appears to be seriously menaced either physically or mentally by the prolongation of captivity, and who would probably be saved from this danger by internment in Switzerland."

If the person's disabilities increased so as to bring him within the category entitled to direct repatriation, he was to be sent home.

In 1917 the Netherlands Government offered to receive in all 16,000 persons, British and German, divided into three categories: (1) invalid combatants (7,500); (2) officers and non-commissioned officers who had been in captivity for 18 months (6,500); and (3) invalid civilians (2,000). This offer formed the basis of the agreement made between the British and German Governments at The Hague in June 1917. By that agreement the schedule of disabilities for the invalids was the same as in the case of Switzerland, except that the British Government insisted with the assent of Switzerland that tuberculous patients should go to that country. Much resentment was felt in consequence of the exclusion of privates who had been 18 months in captivity from the benefit of this agreement. But the British delegates were powerless. Every attempt to induce the German delegates to agree to their inclusion was vain.

The provisions of the agreement arrived at in 1917 were largely extended at a further meeting in 1918, by which all warrant and non-commissioned officers, as well as men who had been prisoners of war for more than 18 months, should, with exceptions, be repatriated, head for head and rank for rank.

General Treatment.—So far an attempt has been made to show how the principal articles of the Hague and Geneva Conventions relating to prisoners of war were applied in Great Britain and Germany during the World War. It remains to be considered how far the over-riding principle laid down in Article 4 of the Hague Convention was observed. That article requires first, that prisoners must be treated with humanity; and second, that all their personal belongings, except arms, horses and military papers, shall remain their property.

With regard to the second requirement charges were made against both armies that this obligation was not observed, and it cannot be doubted that on both sides the wounded were sometimes on their first capture relieved of valuables. But this was not due to any official action; it was due to the unauthorized and wrongful acts of individuals. In respect of one matter only was there anything which could be treated as an authorized disregard of this article. British prisoners often had their boots taken from them by the Germans, either at first capture or later even in the camps in the interior of Germany. This was justified by the Germans on the ground that a man's boots were as much a part of his military equipment as his arms, and that therefore they were entitled to take them away. This claim seems only specious; the practice it sought to support or excuse certainly had the most cruel results in many cases, as men were forced to go about without any covering on their feet, or, if the boots were replaced, as they sometimes were, by wooden clogs, the men suffered much, especially during the winter or in mines from that unaccustomed footwear. However, in other respects this part of the article appears to have been fairly observed, though a somewhat liberal construction was placed on the expression "military papers" by both sides.

We turn now to the other part of the article, which enjoins that the prisoners must be treated with humanity. There existed during the war much misconception with regard to the

treatment of prisoners in Germany, partly owing to the fact that only stories of horrors were published in England and the Allied countries, partly owing to the prominence given to this subject as a method of Allied war-propaganda, in the dramatic form of cinematograph films, and notably in the pictures relating to the work of Mr. Gerard, the American ambassador.

Some of the stories thus circulated were untrue. As an instance, it may be recorded that every story as to the tattooing of prisoners by the Germans, to which great prominence was given, pictures of the alleged victims being produced in the cheap illustrated papers, was, as far as possible, carefully investigated and was in no case shown to have any foundation. But the stories had their effect, for an idea got abroad that a prisoner once in the hands of the Germans was subject to every kind of indignity and cruelty.

It is possible now to weigh all the evidence, and express a judicial conclusion unaffected by the passions of war. The materials for doing so are ample. In the summer of 1915 a committee, presided over by Lord Justice Younger, was appointed by the British Government to enquire into the treatment by the enemy of British prisoners of war. As far as possible, each escaped or repatriated prisoner was examined by a person experienced in taking evidence, and arrangements were also made by the committee for examining the prisoners interned in neutral countries. In all, over 3,500 persons who had been prisoners in Germany, including 445 officers and 90 medical officers, were examined by this committee during the war, and most of their statements were printed and all indexed. After the Armistice the committee was asked to arrange that every returned prisoner should have an opportunity of making any complaint he wished. A questionnaire was carefully prepared and handed to every returned prisoner on his arrival at one of the dispersal camps to which all prisoners were sent before being allowed to return home. Each company of returning men was addressed by the person in charge of the investigation, and he impressed on the men the importance of stating frankly whether there was any complaint that they desired to make, and, if so, what it was. The result was remarkable. Out of not less than 170,000 forms issued only some 59,000 were even returned, and of these only about 22,000 contained information of any value whatever.

While this information was being collected, the then Attorney-General, Sir F. E. Smith (afterwards Lord Birkenhead), appointed a further committee to enquire into the breaches of the laws of war, the sub-committee dealing with prisoners being under the presidency of Mr. Justice Peterson. This sub-committee carefully considered the whole of this mass of evidence, and, in addition, the reports, nearly 2,000 in number, of the American and Dutch representatives who visited the camps. The German military law was also carefully studied.

Information was thus obtained with regard to 57 camps for officers and 78 main camps for men, besides the working camps, the number of which, shown by lists (admittedly not quite complete) from time to time furnished by the German authorities to the Netherlands minister, was 7,157. There were certainly not less than 7,500 places in all where one or more British prisoners were at one time or another confined, in addition to the camps on the eastern and western fronts, which are left for separate consideration.

The result of the investigation was that complaints, some uncorroborated, some trivial and some very serious, were received as regards 929 places, in only 349 of which—rather less than 5% of the whole—did a first study of the evidence seem to call for further examination.

It is clear, therefore, that no general charge of inhuman treatment is well-founded; it is, however, true that, apart altogether from the camps on the eastern and western fronts, there were actually, if not proportionately, a large number of cases in which the German treatment of British prisoners was certainly bad, and, in some cases, very bad.

To form a just estimate of the gravity of the situation so disclosed, consideration must be given to the differences of the

military law and disciplinary practice of the two countries, and to the personal characteristics of the two peoples. With regard to the former, it is not necessary to repeat what has been said before about the severity of the German military law, and in actual practice the officers and non-commissioned officers in the German army are accustomed, apparently without lawful authority, to ill-treat their men physically in a way which would not be tolerated in England. Moreover, the German is naturally more amenable to strict discipline than the average Briton. Much of the ill-treatment complained of in the camps resulted from one or other of the causes above indicated; for the rest a disregard of the German military law or the regulations made for carrying that law into force was the main contributing cause.

In this connexion the attitude of the civilian population cannot be ignored. The anger aroused by the entry of Great Britain into the war induced on the part of German men and even German women cruelties which any decent person must look upon with disgust. It was inevitable that the passage of wounded prisoners from the battle-front to the interior of Germany should be attended with suffering. But that men grievously injured should be subjected to insults and physical ill-treatment is horrible, and that women bearing the Red Cross should throw water on men crying in agony for a drink, or should show to famished men soup and then pour it on the ground rather than allow them to partake of it is conduct almost incredible in its brutality. But such things occurred, not once or twice, but frequently in the early months of the war, and even later the conduct of civilians outside the prisoners' camps is worthy of the severest condemnation. Happily, however, passions were allayed, and after the first year of the war prisoners passed through from the front without being subjected to the insults and ill-treatment which unhappily were common at first.

Again, it was inevitable that, owing to the state of unpreparedness and want of experience of all the belligerents, much discomfort and suffering should be caused to those captured early in the war. This is passed over as being practically unavoidable, and in what follows, unless otherwise clearly stated, the conditions recorded are those after the organization was or ought to have been fairly complete.

Officers.—The treatment of officers in a camp depended very much on the commandant, and, to some extent, on the personality of the general of the army corps district in which the camp was situated. As officers were under no obligation to work, one grievance which was so fruitful a cause of trouble in the men's camps did not exist in their case.

In some camps where, as at Crefeld, the commandant was a gentleman, no valid complaint can be made of the treatment. In others, especially in the X. Army Corps district, where the malign influence of Gen. von Hähnisch was paramount, some of the commandants were neither gentlemen nor capable of understanding the feelings of gentlemen, and there was continual trouble. At Clausthal and Holzminden, of which the two brothers Niemeyer were commandants, the state of affairs was intolerable. There were continual arrests for trivial offences and endless pinpricks on both sides. But, worse than this, the guards had orders to use their bayonets and rifles without adequate cause. On one occasion an officer, for looking out of a window, was shot at by order of the commandant at Holzminden, but fortunately not hit. At Strohen, another camp in this district, two officers were seriously wounded in a bayonet charge ordered personally by the commandant because a knot of them had gathered near a prohibited part of the camp.

One matter gave rise to much resentment. It was right and proper for the Germans to make occasional strict searches in view of the continual attempts to escape; but their method of carrying them out with detectives from Berlin assisted by police dogs which prowled round the completely stripped officers was offensive in the extreme.

But these were exceptional places and incidents. In general, the officers commanding were gentlemen, who treated their charges with courtesy and consideration, though in most cases there was occasional friction owing to the propensity of the

young officers to attempt to escape, and, in some measure perhaps, owing to the inability of German officers to understand the exuberance—even in captivity—of British subalterns.

Men in the Main Camps.—In the main camps the treatment on the whole seems to have been reasonable, and in some cases more considerate than might have been expected. There was the usual trouble from the enforcement of a discipline far more severe than that to which the prisoners had been accustomed in their own army; from the violence with which the German non-commissioned officers treated offending prisoners, and, up to quite late in the war, from the use of savage police dogs in the camps, which the German Foreign Office declared to be "a military necessity, in view of the large number of prisoners of war in Germany," adding that, "having regard to the inferior number of prisoners in England no comparison can be drawn between conditions in the two countries." Trouble, and even loss of life, was caused by the too frequent use of firearms in some camps, as, for instance, at Wittenberg, where on one occasion men were ordered to return to their huts on a given signal and the laggards were fired on. But such incidents were not general, and occurred only in camps where the commandant was quite unfit for his post. In most cases the prisoners were treated fairly, if strictly; in a few, of which Friedrichsfelde may be taken as an example, at all events in its later stages, everything seems to have been done to make the prisoner's lot as little irksome and unpleasant as possible. An exception must be made in the case of Langensalza, where the treatment was from first to last rough in the extreme, a roughness which culminated just after the Armistice in the shooting by the guard, hurriedly called upon the scene, of a number of prisoners who were pulling down a building, a proceeding condemned by the German Court of Enquiry as a breach of Article 4 of the Hague Convention.

Working Camps.—Still leaving out of consideration the camps in the occupied districts on the eastern and western fronts, the great bulk of the ill-treatment occurred in the working camps, and by a curious paradox, it is in them that the best treatment is to be found. The ill-treatment was due to two main causes: first, to the fact that, except in very large working camps, the person in charge was a non-commissioned officer, and, second, to the passive resistance and in some cases the active insubordination of the British prisoners.

The non-commissioned officers, trained in the school of the German army and unrestrained by the presence of a superior officer, treated the prisoners in the way in which the rank and file of the German army have so often been treated. Men who refused to work, or in the opinion of the guards did not work hard enough, were kicked, spat upon, beaten with sticks, whips, clubs, rubber tubing, mining hammers and the butts of rifles. Those who escaped and were recaptured not infrequently received severe beatings before they were reported as recaptured and were formally punished for their offence. And all this was done notwithstanding the regulations, which, after laying down rules in the main reasonable enough for the use of arms by the guard, continue as follows (the quotation is from the instructions in force in the II. Army Corps district):—"Blows with the hand or fist or with sticks or clubs and kicks are forbidden. Except in the most exceptional and unusual cases it is inexcusable to lay hands on a prisoner."

Even where the non-commissioned officer was lawfully inflicting punishment, he would often by his perverse ingenuity add to its severity. Men were made to stand at attention on hot asphalted roofs, or before coke ovens, where they were nearly roasted, or sometimes in exposed positions without an overcoat in the freezing atmosphere of a winter's night. At more than one mine, the dark cells, in which, according to the German law, prisoners of war under punishment were obliged to pass their periods of close arrest, were constructed in close proximity to the main steam pipe and became so hot that the men had to strip themselves almost to the skin.

For all this there is no excuse or palliation possible; happily, however, there is another side to record. At some large German works the employers seem to have taken a real interest in their

PRISONERS OF WAR

prisoners, and to have done whatever in them lay to make their lot endurable and even comfortable.¹ On the farms and similar places, the relations between prisoners and their employers were frequently, as in Great Britain, even cordial, and more than one repatriated British prisoner has spoken warmly of the kindness and consideration with which he was treated, though such cases were, of course, not common.

The impression produced by the study of all the available material is that there was neither in the main nor the working camps in Germany any officially recognized ill-treatment of prisoners; that there was, nevertheless, in many cases much cruelty by individuals, and that when as occasionally, but far too infrequently, happened, a prisoner could bring home to the authorities that some individual had exceeded his powers and acted outside the regulations, the offender was punished, sometimes by being sent away to the front, sometimes by a sentence to a term of imprisonment. On the other hand, it is also clear that in some cases the prisoners were treated, not only with humanity, but with kindness.

The reason for these contrasts is to be found in two things. First, the personal character of the man in charge, and, second, the independence of the army corps commanders, and even to some extent of the camp commandants, who not only placed their own interpretation on the regulations, but sometimes acted in deliberate defiance of them.

Men in the Occupied Districts.—While the above represents the considered opinion which results from the study of the very voluminous material available with regard to the camps in the interior in Germany, the same conclusion cannot be reached when the evidence dealing with the camps in the occupied districts is examined.

The cruelties inflicted on the prisoners in these places had their origin, and from the German point of view, their justification, as reprisals for alleged ill-treatment of Germans in British hands. It is not proposed to give here an account of the reprisals enforced on one side or the other, more than to allude to the severe conditions under which the first captured German submarine officers were interned in Great Britain, which resulted in the German Government retaliating by selecting from among the officers in their hands who bore well-known names (including among them the son of the former British ambassador to Berlin) and imprisoning them under exceptionally rigorous conditions. Most of the reprisals, while unpleasant enough for the victims, were not such as to amount to real cruelty.

But it is not too much to say that the treatment of the prisoners of war on the eastern and western fronts must, so long as the terrible story is remembered, bring indelible disgrace on the German nation, and on those responsible for the appalling cruelty inflicted on defenceless men. It was quite deliberate, as the following facts will show.

Eastern Front.—In the spring of 1916, German prisoners of war were sent to work at Rouen and Havre, and in May the German Government informed the British Government that it had in consequence decided to send 2,000 British prisoners to the occupied Russian territory to work under similar conditions to those existing at Havre and Rouen. They were accordingly sent, divided into four companies of 500 each, to four main camps, from which they were sent in smaller parties to work on numerous farms and in road-making and tree-felling. There is no serious complaint to make of the central camps, but at the others the conditions were very hard, the accommodation bad, and the *unter-offiziers* rough.

On Feb. 7 1917, the British Government received a German *note verbale* in which complaint was made that a considerable number of Germans were detained behind the British front in France, where it was alleged the "prisoners suffered from inadequate food, defective accommodation . . . as well as being subjected to hard work and irregularities in the matter of mails," and that they were exposed to German gunfire which "has resulted in several of them being killed." The Germans re-

quired that their men should be removed to a distance of at least 30 km. behind the firing-lines and "provided there, with accommodation in accordance with the season of the year and hygienic needs." In default of the British Government notifying their compliance with these demands by Feb. 1 (the *note verbale* was dated Jan. 24 and received on Feb. 7), "a number of British prisoners will be transferred from camps in Germany to the area of operations in the western theatre of war where, in respect of employment, accommodation, food, and the question of mails, they will be treated in a manner corresponding to the practice of the British military authorities"—which means, of course, the practice alleged by the Germans, *i.e.* insufficient food, defective accommodation (only tents), hard work and irregular mails.

The British Government, in a *note verbale* for transmission to the German Government, dated Feb. 8 1917, gave the explicit assurance that the prisoners received the same food as the British troops, that 75% were in huts, the remainder being like many British troops in specially warmed tents with floor boards, that strict orders had been given against their being employed within the range of German gunfire though it was regretted that one man had been wounded by a shell which must have been fired at exceptionally long range, this being the only casualty which had occurred.

Within ten days of the date of the British reply, 500 men were sent, not to the western but to the eastern front, and they were "officially informed" that they would be sent to the trenches between Riga and Mitau and remain within the artillery zone by way of reprisal. On Feb. 25 these 500 men were forced to march 35 km. up the frozen river Aa, often through snow-drifts knee deep. Sledges followed to pick up the men who broke down from exhaustion, while the escort of Uhlans drove the stragglers on with lances and whips. Those who fell were robbed of their kit and property. Of the 500 who started, between 120 and 130 are said to have collapsed on the march. "They were brought in by transport later, but through their lying in the snow they were frost-bitten in the hands and feet."

Arrived at their destination, the men were kept waiting outside a "cavalry tent built on the ice of (marsh by) the river. It had wire beds on three racks, the bottom one being about one foot from the ground, so that the weight of a man's body weighed it down till he was lying on the snow or the ice."

The next morning they were paraded, and a notice was read out giving the reasons why they were there. The substance of this notice is given by one of the British prisoners who heard it, as follows:—

"You are here on a reprisal because the English have German prisoners working in the firing-line in France. They have had accommodation, bad food, bad treatment; they are under fire and 36 men have lost their lives. In return, you are to work here in the firing-line and will get bad treatment, bad food, bad accommodation, and 36 of you have got to die."

The way in which it corresponds with the substance of the *note verbale* of Jan. 24, already quoted, which the soldier who gave the evidence could not possibly have heard of, cannot escape notice, any more than the fact that the accommodation provided corresponds with the complaint that some of the Germans at Havre and Rouen were lodged in tents.²

The threats contained in the notice were carried out to the letter. The accommodation was bad, the treatment was bad, the food was bad, and numbers of men died, while more lost toes, fingers or hand through frost-bite.

The tent was a large cavalry tent pitched on the frozen marsh, with a foot or more of snow and ice inside and frequently under shell-fire. There were some small stoves, but no fuel or entirely inadequate fuel was provided. The "revier Stube" was a wretched peasant's cottage (in which the guard also was quartered) in charge of a brutal Sanitätsler. Men in the last stages of illness were sent by sledge to Mitau. When the thaw

² When the men had been in this place for a week the "German Government informed the Netherlands minister at Berlin, in a *note verbale* dated March 5, that British prisoners of war had not yet been sent quite close to the German firing-line on the Russian front."

¹ In some places the prisoners were even taken periodically to the local cinema, not always at their own expense.

time the tent was moved to Pinne, on the other side of the river, where deep mud took the place of snow and ice inside the tent.

There was no water supply; such water as there was, was obtained by melting ice from the river or by digging down into the marsh, where filthy polluted water was obtained. Most of the men had no wash during the whole time they were there. The treatment was bad. Were it not established beyond the possibility of doubt, the story would be unbelievable. Men were driven out to work—breaking ice on the river, felling trees, making and repairing trenches under fire—when they could hardly stand, and had to be supported by their comrades to and from their work. One man died while being carried home; another, who had fallen exhausted on his way back to camp, was shot at point-blank range by the sentry; while a third man, who did not turn out quick enough one morning, was first abused and then attacked with a bayonet by the Sanitater; further investigation disclosed the fact that he had been dead some hours, frozen in his bunk. The only punishment was tying to the post outside the tent for two hours after the men returned from work, under conditions hardly differing from crucifixion. A sergeant-major, having been urged by the interpreter to write home how they were being treated, eventually did so: "next day," he proceeds, "I got the letter back marked 'five days strong arrest.' After being hard at work from 6 A.M. to 6 P.M., I was tied to the pole from 7 P.M., during 36 degrees of frost." This is corroborated by several witnesses.

That this treatment was deliberate and inspired by higher authority is evident from the fact that the sergeant-major says he obtained a copy of the orders from the guard, which stated "that no mercy was to be shown to us; we were men who had, every one of us, assisted in stopping the Kaiser's army from going to Paris; and they were to think of their comrades who were being brutally treated in France. Any soldier failing to carry out these orders was to be severely punished."

The guards were given three-quarters of a loaf each day, the prisoners, doing hard work, received one-sixth of a loaf. The guards were given good, thick soup; the prisoners, soup "that you could drink straight off." To such straits were the men reduced that it is recorded by more than one witness that the men became so ravenous that they would eat anything. "There were," says one, "many unburied Russian bodies lying round the camp. Some men were so reduced that when they saw any bones they would rush at them and eat them like a dog. It was pitiful to see men reduced to such an animal stage." No parcels were allowed before April, and no letters. When the remnants of this unhappy company returned to Mitau, 20,000 parcels were found stored. Had they been forwarded much suffering might have been avoided and lives saved.

The result of this inhuman treatment was what might have been expected. At the end of April 1917, there were 77 men left in the camp out of the 500 driven there in February. Of these, no fewer than 47 were certified by the German doctor as unfit to leave their beds. No less than 23 had died from exposure and starvation—some 16 in the camp, the rest in hospital at Mitau, besides those killed by the sentries or permanently injured by shell-fire or frost-bite.

There can be no doubt whatever that the sufferings endured by this unfortunate 500 were directly due to someone in authority in Berlin. The terms of the notice read out to the prisoners and of the orders given to the guard are in exact accordance with the terms of the *note verbale* of Jan. 24 1917.

Western Front.—The story of the treatment of the prisoners on the western front is not less terrible, indeed in some respects it is worse in that their sufferings were more prolonged, though they were not exposed to the same climatic conditions as their comrades in Russia. There is overwhelming evidence in this case also of the deliberation with which the suffering was inflicted.

In April 1917 it was agreed, after the communications of January and February mentioned above, that neither belligerent would employ prisoners within 30 km. of the firing-line, and on April 28 a telegram was sent by the British authorities informing the German Government that orders had been issued

that all German prisoners were to be removed. On May 30 a further telegram was sent stating that they had all been withdrawn to a distance of 30 km. from the firing-line, and requesting immediate information that the British prisoners had been so withdrawn on the eastern and western fronts. No reply was received till July 4, when the British minister at The Hague transmitted a communication from the German Government stating that "there can be no question in any case of intentional retention or concealment of British prisoners," and on July 9 a further communication was received, dated Berlin June 15, saying "that the withdrawal of British prisoners of war in the German fighting zone to a distance of 30 km. behind the firing-line has been completed everywhere."

On July 2 the British and German representatives at The Hague had made the following important agreement:—

"Reprisals against combatant and civilian prisoners of war may only be carried out after at least four weeks' notice of intention so to do has been given"; and second, "all captures are to be notified by the captor State to the other State with the least possible delay; every prisoner captured is to be allowed to communicate at once with his family and is to be provided with the means of doing so and the dispatch of his communication is to be facilitated; as soon as practicable after capture every prisoner is to be enabled to inform his family of an address at which they can communicate with him."

The statements with regard to the removal of the prisoners were not true. From early in 1917 up to the Armistice prisoners were kept by Germans within 30 km. of the front line and were there subjected to the most cruel treatment. After the above-mentioned agreement, and up to the date of the German offensive of March 1918, their number was probably not large, but after that date thousands were so detained under very bad conditions. No notice of the fact that they were to be so detained as a reprisal was ever given to the British Government.

In April 1917 a notice entitled "Conditions of respite to German prisoners" was handed at Lille to a British noncommissioned officer to be read out to his fellow-prisoners. It runs as follows:—

"Upon the German request to withdraw the German prisoners of war to a distance of not less than 30 km. from the front line, the British Government has not replied; therefore it has been decided that all prisoners of war who are captured in future will be kept as prisoners of respite (sic). Very short food, bad lighting, bad lodgings, no beds, and hard work beside the German guns under heavy shell-fire. No pay, no soap for washing or shaving, no towels or boots, etc."

The notice proceeds to the effect that prisoners are to write home of their sufferings and that "no alteration in the ill-treatment will occur till the English Government has consented to the German request" and then the prisoners would be removed "to camps in Germany, where they will be properly treated, with good food, good clothing." Stationery would be supplied and "all this correspondence in which you will explain your hardships will be sent as express mail to England." Similar notices were read out at several other places. The threats were carried out to the letter. The accommodation was everywhere and always as bad as it could be. In the spring of 1917 prisoners were confined at Lille in conditions comparable only to those of the "black hole" of Calcutta, the crowding was terrible, there were no washing arrangements, and the only sanitary accommodation took the form of tubs in the rooms. The same conditions were renewed or continued in 1918; in the spring of that year the men were told that they were being badly treated as a reprisal. Prisoners were sent to places behind the lines, where they had to work for eight or nine hours on end and even longer on entirely insufficient food. The evidence of over 2,300 men has been obtained with regard to 78 of these places, at 20 of which they were exposed to Allied shell-fire which caused many casualties, while at 38 they were engaged in work directly connected with the operations of war, being required in some cases actually to take up ammunition to the German guns. They were forced to do this by brutal ill-treatment, and were worked till they could do nothing more and either died or were sent back to Germany mere wrecks of their former selves. Men died in the train, their bodies being taken out at stations on the way; many more died within 24 hours of their arrival at the

hospital to which they were sent, and often a large percentage (up to 30 % it is said in some cases) within the next three or four weeks. Their physical condition is vouched for by 33 medical officers who were prisoners: 10 of them immediately behind the lines who saw what was going on, and the remainder detained in the interior of Germany who saw and tended the prisoners on their arrival there.

The under-feeding of the prisoners on this front was aggravated by three things: First, the Germans did not notify the capture of large numbers of them in obedience to the Hague agreement of 1917; second, the prisoners were forced to give as their address some camp in the interior of Germany to which parcels were sent for them and, except in a few cases, not forwarded; third, steps were taken to prevent the French and Belgians giving the prisoners any food.

The *Kommandantur* at Mons on April 4 1918 issued a notice in French of which the following is a translation:—

"Conversation with prisoners is absolutely forbidden, as is giving them letters, food, or anything else. Breaches of this regulation will be punished by imprisonment for a maximum of three years or a maximum fine of 10,000 marks."¹

This was repeated on July 28 and on Sept. 9 1918 the *Kommandantur* again called attention to the matter, the notice of the latter date containing a passage of which the following is a translation:—

"Notwithstanding this warning, frequent breaches of the regulation have been reported. The *Kommandantur*, being responsible for strictly maintaining order, has instructed guards to use their firearms when it becomes necessary so to do."²

This was no mere threat. Many civilians, women among them, were shot for attempting to help the starving prisoners, and many prisoners were shot on the spot even for attempting to pick up the remains of food which they saw in the road as they marched along.

This treatment was continued right up to the Armistice, when prisoners in the last stages of exhaustion and starvation stumbled into the British lines hardly recognizable as British soldiers. The High Command had faithfully kept their promise of "very short food, bad lighting, bad lodgings, no beds and hard work beside the German guns under heavy shell-fire."

PRISONERS OUTSIDE EUROPE.—Something must be added with regard to the treatment of prisoners elsewhere than in Europe, if only because serious complaints were made on both sides as to their treatment with regard to accommodation and food, especially in East Africa. There can be no doubt that much suffering was endured by prisoners of both nationalities in this part of the world; but it was mainly due to the conditions of the campaign and to the climate, while on the British side there appears to have been much justification for the complaints which were made against individual Germans for their want of consideration for the devoted men and women missionaries whom the fortunes of war had brought into their hands.

Turkey.—Little can be said with regard to the application of the Hague Convention by Turkey, because the Government of that country made practically no attempt to conform to the regulations contained in it. Their treatment of prisoners varied from an almost theatrical politeness to the great, to complete indifference to suffering—almost to barbarism—in the case of men of little esteem.

These oriental characteristics may be best illustrated by the fate of the British prisoners captured on the fall of Kut el 'Amara at the end of April 1916, when, as Enver Pasha stated, they became "the honoured guests of the Turkish Government." The

¹ The original wording was:—

"Il est absolument interdit de parler aux prisonniers ou de leur passer des lettres, des vivres, ou d'autres objets quelconques. Les infractions à cette prescription seront punies d'un emprisonnement pouvant s'élever à 3 ans, ou d'une amende pouvant atteindre 10,000 marks."

² The original wording was:—

"Malgré cette défense, de nombreuses infractions ont été signalées. La *Kommandantur* ayant pour tâche de maintenir l'ordre le plus strict, les soldats de surveillance ont reçu l'instruction de faire usage, le cas échéant, de leurs armes à feu."

officers were sent by steamer to Bagdad and thereafter drafted to various camps in Anatolia. The men were marched 100 m. to Bagdad, in stifling heat, with no sort of organization for food transport or medical care of those worn out by the privations of the long-drawn-out siege. The Turkish commandant promised that the day's march should not exceed eight miles. He kept his promise for one day, and thereafter the men were forced to march from 12 to 18 m. a day, herded like sheep by mounted Arabs who flogged forward the stragglers. At night they lay out on the open ground without any shelter. Many fell out and died. At one point 350 men were left behind in a sort of cowshed, so sick as to be unable to move, and were picked up by the already overcrowded boats, where there was room only for the most desperately ill to lie down. Arrived at Bagdad, all but 500, who were too ill even for the Turks to force them forward, were sent on a 500-m. march to places where they were to work.

Out of a total of 13,670 of all ranks believed to have been captured at Kut, in the course of two and a half years 2,425 escaped or were repatriated, 2,611 are known to have died, while 2,200 were missing, and there were left in the hands of the Turks only 7,424, or little more than half of those captured.

Up to Dec. 1917 the Ottoman Government steadily refused to permit neutrals to inspect the camps, and though this concession was then made, it was so worded as in effect to be useless.

Bulgaria.—If due allowance is made for the backward condition of the country, it must be admitted that the treatment by the Bulgarians was correct, though complaint was made that British soldiers were flogged for disciplinary offences. This is permitted by the military law of Bulgaria but after representations were made on the subject the practice was abandoned in the case of British soldiers.

The food given the prisoners was the same as that given to the Bulgarian soldiers, and the hospital treatment was not less good than that given to their own men. The accommodation was rough but in general no worse than that of the inhabitants of the country. Every effort appears to have been made to improve conditions where they were remediable, and the authorities seemed anxious to treat their British prisoners with consideration. An unusual amount of liberty was accorded to the prisoners, and there is no little evidence of the kindness and friendliness of the Bulgarian civilians to the British.

Austria.—The few British prisoners captured by Austria were treated with consideration and in accordance with the provisions of the Hague Convention.

NEGOTIATIONS DURING THE WAR.—During the World War a notable step was taken in arranging for meetings between representatives of the belligerents for the discussion of matters relating to prisoners of war. In the spring of 1917 meetings had taken place between French and German representatives with useful results, and, largely owing to the insistence of Lord Newton, who was then in charge of the Prisoners of War Department of the British Foreign Office, a meeting between German and British representatives was arranged and took place at The Hague in June. Great Britain was represented by Lord Newton, Lord Justice Younger and Gen. Belfield, and Germany by Gen. Friederich and two others, the meetings being presided over by M. van Vredenburg on behalf of M. Loudon, the Netherlands Minister of Foreign Affairs. At this meeting arrangements were made for the repatriation of disabled combatants, for the internment of invalid interned civilians, for the repatriation of medical personnel still retained by the belligerents, and for the mitigation of certain punishments inflicted on prisoners of war. It was agreed that reprisals should only be carried out after a month's notice of intention to do so had been given and it was also agreed that all captures were to be notified with the least possible delay.

This meeting was followed by one which lasted from June 8 to July 14 1918, at which the British representatives were Lord Cave, Lord Newton and Gen. Belfield, the first-named being obliged to return before the agreement was signed. It contained no fewer than 60 articles with six annexes thereto, and dealt with the following subjects: the repatriation of invalids;

the internment in a neutral country of prisoners who had been a long time in captivity; the protection of prisoners after capture; prisoners retained in an area of operations; notification of capture; equipment and organization of camps; food; punishments; help committees; relations with protecting powers; parcels and postal services; and the publication of the agreements in the different camps. Much was done by these two meetings to translate into a concrete form the principles laid down in the Hague Conventions, and to mitigate the lot of the prisoners, though the full benefit of the second agreement was never realized as it was never formally ratified.

In Dec. 1917 Lord Newton and Gen. Belfield met Turkish representatives at Berne under the presidency of M. Ador, of the Swiss Political Department, and an agreement was drawn up on lines similar to those of the German agreements.

QUESTIONS FOR THE FUTURE.—The foregoing investigation of the operation of the Hague Convention during the World War leads one inevitably to ask whether it is desirable and practicable to make any substantial amendment to that Convention. It is a most difficult question to answer, for, although not generally recognized, the whole problem is military rather than humanitarian. While of course all active ill-treatment should be prohibited, the lot of a prisoner must not be made so attractive in comparison with that of soldiers in the firing-line as to afford a temptation to them to desert or to do anything incompatible with their military duty. Further, while it is possible for the voices of humanity and charity to make themselves effectively heard in times of profound peace, it is useless then to formulate regulations which public opinion, stirred to its depths by alleged misdeeds of the enemy, will not allow to be observed, and which the military authorities will disregard in time of war. All that can be usefully accomplished is to put into the form of rules those principles which the good sense of all civilized nations accepts as correct, and for this purpose to use the experience gained during the World War, of which not the least important part was the value of direct conference between representatives of the belligerents during active hostilities for the purpose of dealing with the detailed application of those principles.

But it does seem desirable that regulations should be made dealing with the case of civilians found in any enemy country at the outbreak of war, for it is improbable that in any future war of nations civilians will be allowed to return home or to remain at large in view of the means of communication which modern science has made possible.

The value of the inspection of prisoners-of-war camps by the accredited representatives of the protecting State has been made abundantly clear, and their right to visit the camps, which was the result of an agreement made early in 1915 between the British and German Governments should be made permanent. It will, however, be extremely difficult to reconcile the desires of the humanitarians and the military authorities with regard to camps within the area of hostilities, though it will probably be found possible to come to some agreement defining the nature of the work on which prisoners of war may not be employed, and an attempt should be made to make more clear than it is at present the obligation of the captors with regard to the feeding and clothing of the prisoners in their hands.

For military reasons there would be no chance of obtaining a general assent to the prohibition of reprisals, but provisions similar to those contained in the agreements with the German and Ottoman Governments requiring notice before reprisals are made might be accepted.

Finally, those agreements made during the war with regard to the repatriation of disabled prisoners, and the conditions on which a prisoner should be entitled to internment in a neutral country if accommodation could be found, might be made of universal application.

There remains the most difficult question of all: whether it is possible to provide penalties for the infraction of any regulation which may be made, and to establish a tribunal with authority to punish individuals and States. Articles 227-229 of the Peace Treaty with Germany, satisfactory from one point of view,

savour too little of the calm administration of justice. They are not reciprocal, the vanquished are given no right to have judicially investigated any complaints they may have against the victors. It would be far more satisfactory to have an alleged "atrocity" investigated than that, for want of public investigation, an unfounded legend of brutality should grow up.

It is perhaps too much to expect that, at the conclusion of a war in which the victors have made great sacrifices and undergone great suffering, they should take steps to establish a court for the trial of charges against their own people, but if provision had been made in time of peace for the establishment of a court to investigate all charges of wrong treatment in time of war the victors would not depart from their agreement. The establishment of such a court may well occupy the attention of statesmen and international lawyers.

Agreement between the British and Ottoman Governments respecting prisoners of war and civilians: Misc. 10 (1918), cd. 9024. Work of the Central Prisoners of War Committee 1916-1919: *Revue Internationale de la Croix Rouge* (No. 26, Feb. 1921). Report of the Joint Committee to enquire into the organization and methods of the Central Prisoners of War Committee, cd. 8615.

Up to Jan. 1922, neither the British Government Committee on the treatment by the enemy of British prisoners of war, nor the Committee on the Breaches of the Laws of War, had published any general report; nor had the Reports of the representatives of the Netherlands Government been published. (R. B. D. A.)

PROFITEERING.—The word "Profiteering" was introduced in 1919 into an Act of Parliament, and thus may be said to have obtained official recognition as part of the English language. It had become current colloquially quite early in the World War. The following implicit definition was given by Sir Auckland Geddes (as president of the Board of Trade) in Parliament on the second reading of the Profiteering bill (1919):—"To profiteer is to make an unreasonably large profit, all the circumstances of the case being considered, by the sale to one's fellow-citizens of an article which is one or one of a kind in common use by the public, or is material, machinery, or accessories used in the production thereof."¹ As an urgent social and economic prob-

¹ Hansard, vol. 129, No. 114, Col. 543, Aug. 11 1919.

lem the conception of "profiteering" was a new one as well as the name attached to it, since the possibility of unreasonably high profits being reaped on a large scale to the public detriment from the sale of articles in common use was a direct outcome of the conditions of disorganized trade and world-shortage of commodities which resulted from the World War. It is clear that under normal economic conditions high profits do not necessarily involve high prices, but may even be obtained as a result of greater efficiency of organization or production. It is probably true to say that before the war, as a rule, a free market and plentiful supplies afforded, in the case of most commodities in general use, an effective safeguard against excessive profits based on excessive prices.

It was no doubt partly with this consideration in view that (to meet the demand for a clearer definition of the offence) a provision was inserted in the bill in Committee, laying down that a rate of profit not exceeding the pre-war rate should not be deemed "unreasonable." It is with profiteering in this technical sense that this article deals, and not with the wider economic problems affecting profits as such.

The Profiteering Act, 1919, was thus a temporary measure designed by the British Government to meet peculiar circumstances. It was a measure "to check profiteering," and accordingly was framed to avoid, so far as possible, any interference with legitimate commercial enterprise. The great difficulty presented by legislation of this kind is to design an instrument of such accuracy, and to use it with such precision, that it shall deal effectively with the evil against which it is directed, without hitting the sensitive organism of trade and industry, the recovery of which was in itself an essential factor in the removal of those conditions of shortage and high prices of which profiteering was to a large extent a symptom. How far the Profiteering Acts succeeded in solving this difficulty is a matter of opinion, but this was the problem they had to deal with.

The main powers conferred upon the Board of Trade by the Profiteering Act, 1919, may be summarized as follows:—(a) to investigate prices, costs and profits at all stages; (b) to receive and investigate complaints regarding the making of excessive profits on the sale of any article to which the Act was applied by the Board of Trade, and after giving the parties an opportunity of being heard either to dismiss the complaint or to declare the reasonable price for such articles, and to order the seller to refund to the buyer any amount paid in excess of such reasonable price. The Board also had power, where it appeared to them that the circumstances so required, to take proceedings against the seller in a Court of Summary Jurisdiction; (c) to obtain from all sources information as to the nature, extent and development of trusts, and similar combinations.¹

The Act was applied by the Board of Trade by a series of orders to practically every article of ordinary everyday use, including all articles of wearing apparel, household utensils and requisites, articles for mending and knitting, furniture, building materials, drugs and medicinal preparations, medical and surgical appliances and dressings, mineral waters, all articles used for fuel and lighting, tools, weights, measures, weighing and measuring instruments, motor spirit, stationery, and, in agreement with the Ministry of Food, to practically all articles of food the price of which was not otherwise controlled, including milk, bread, fish, tea, coffee, cacao, margarine and meat. Further, in accordance with extended powers given by Section 2 (2) of the Profiteering (Amendment) Act, 1920, the following processes were by order brought within the operation of the Acts: the repairing, altering or washing of articles of wearing

apparel and household linen, etc., the repairing, altering or cleaning of clocks and watches, and the repairing or altering of boots, shoes and umbrellas.

For administrative purposes the Act empowered the Board of Trade to establish or authorize local authorities to establish local or other committees to which the Board might delegate any or all of their powers under the Act (except the power to fix maximum prices). The work fell naturally into two broad sections, viz.: (1) the larger transactions of wholesalers or manufacturers which raise wide questions affecting whole trades or industries, and (2) retail trade, which is much more affected by local conditions. To deal with (1) the Board of Trade set up a Central Committee, with its headquarters in London; to deal with (2) the Board invited local authorities throughout the country to appoint local profiteering committees.

Local Committees and Appeal Tribunals.—Over 1,800 local committees were established in the United Kingdom, and the vast majority continued in existence until the expiration of the Profiteering Acts in May 1921. Their constitution, powers and procedure were defined by regulations made by the Board of Trade, who delegated to the local committees the bulk of their powers under the Act in relation to retail sales. The regulations provided among other things that labour, women, and the retail trade should be adequately represented on local committees; that complaints should, except in special cases, be heard in public; that any member who happened to be a trade competitor of the respondent or otherwise personally interested should be disqualified from adjudicating; that a complaint should be lodged in writing within four days of the sale, and a copy forwarded to the respondent within seven days of its receipt; that a preliminary investigation should first take place, after which if a *prima facie* cause of complaint had been disclosed at least three days' notice should be given to the parties of the date fixed for hearing the complaint; and that both complainant and respondent should always be given an opportunity of being heard. The object of the preliminary investigation was to weed out frivolous complaints. The rule was laid down that it should invariably be held *in camera* and that the names of the parties to any complaint should not be made public until such time as the complaint was heard in public. The Board of Trade also appointed 108 appeal tribunals, to which the seller had a right of appeal against the decision of a local committee. The total number of complaints investigated by local committees during the operation of the Acts (Aug. 1919 to May 1921) was over 4,700; of these some 73% were dismissed. Only 173 appeals were made, of which roughly two out of every five were dismissed. Only 202 prosecutions by local committees were reported to the Board of Trade; in these fines were imposed to the amount of some £1,786, and costs ordered against the seller to the amount of £455. Within the limits laid down by the regulations local committees had full freedom of action and were in no sense controlled by the Department. The Department, however, both by correspondence and through a small staff of six or seven travelling inspectors, kept in close touch with the committees' work, and helped them wherever possible with advice and information. Apart from the work arising out of actual complaints, the local committees had the power to hold general investigations into prices, costs and profit at the retail stage, but comparatively few committees undertook such investigations. The report of the county of London appeal tribunal, which dealt with a much larger number of cases than any other appeal tribunal, has been published as a Parliamentary paper.

Central Committee.—This body, about 150 in number, was widely representative, including among its members manufacturers, traders, consumers, trade-union representatives, economists, representatives of the cooperative movement, etc. Mr. McCurdy, its first chairman, was succeeded after about 10 months by Mr. John Murray, M.P. The Board of Trade made regulations laying down the constitution, powers and procedure of the Central Committee, to which the Board delegated the power (a) to investigate prices, costs and profit at all stages; (b) to investigate, consider and determine complaints regarding unreasonable charges arising out of the wholesale sale of any articles to which the Act was applied; and (c) to obtain information regarding trusts and trade combinations.

The Central Committee rarely met as a committee. Its functions were rather those of a panel, and the work was performed by three standing committees: the Investigation of Prices Committee, the Complaints Committee, and the Standing Committee on Trusts. Every member of the Central Committee was appointed on one at least of these standing committees, which in turn appointed from time to time small sub-committees. These sub-committees, through which the bulk of the work was done, were composed of members of the Central Committee with the addition often of outside persons appointed (in practice at the suggestion of the sub-committee or standing committee concerned) by the Board of Trade.

The Investigation of Prices Committee undertook the investigations into the cost of production of various articles in all stages of their manufacture where they considered it desirable to obtain such information for the benefit of the public or of the Board of Trade. The reports on these investigations were published from time to time as Parliamentary papers: they cover the following subjects: agricultural implements and machinery, aspirin, biscuits, boot and shoe repairs, brushes and brooms, clogs, costings in Government department, furniture, gas apparatus, matches, metal bedsteads,

¹ Powers were also conferred on the Board of Trade by the Principal Act to fix maximum prices, and to authorize local authorities under suitable conditions to buy and sell any article or class of articles to which the Act was applied. These powers were only intended to be held in reserve for use in an emergency. Neither power was ever exercised, with the single exception of the temporary fixing of the price of motor spirit during the railway strike in the autumn of 1919. Further provisions were embodied in the Act (or added by the Amendment Act of 1920) giving the Board compulsory power of obtaining information, providing proper safeguards for confidential information and for secret processes, providing against victimization of complainants by sellers refusing to sell, excluding from the scope of the Acts sales for export or sales by public auction or competitive tender, and laying down maximum penalties by way of fine or imprisonment for persons offending against the Acts.

motor fuel, pottery, standard boot and shoe scheme, tweed cloth, wool and worsted yarns, wool, and the wool-top-making trade.

The Complaints Committee undertook the investigation of specific complaints arising out of transactions or sales other than retail sales. In practice the Complaints Committee became, like the Central Committee itself, a panel, working almost exclusively through sub-committees or tribunals. The procedure was analogous to that of local committees, the complaint being first considered *in camera* by a sub-committee called the Preliminary Investigation Committee, who, if they were of opinion that the complaint did not give sufficient particulars or did not disclose *prima facie* grounds for hearing the complaint, had power (after giving the complainant an opportunity of being heard) either to dismiss the complaint forthwith or to require the production of further or better particulars or grounds of complaint within a stated period, failing which the complaint was dismissed. If the Preliminary Investigation Committee were satisfied that a *prima facie* cause of complaint was disclosed, a tribunal was appointed to hear the case, seven days' notice being given to the parties of the time and place fixed for the hearing. The tribunal had power either to dismiss the case, or (if they were satisfied that an unreasonable profit had been made) to order the seller to repay to the complainant any amount paid by him in excess of the price declared by the tribunal to be reasonable; further, the tribunal might take proceedings against the seller before a court of Summary Jurisdiction. The hearing of all complaints before the tribunal was normally in public, subject to the discretion of the tribunal in particular cases, and the parties could conduct their own cases or be represented by counsel or otherwise. As in the case of local committees, trade competitors or persons otherwise personally interested were disqualified from adjudicating on the tribunal.

The Complaints Committee also investigated specific transactions brought to their notice, even where there was no formal complaint; e.g. cases referred to the Board of Trade by local committees where a complaint against a retailer had been dismissed, but it appeared probable that profiteering had taken place at some earlier stage of distribution or manufacture. The following figures show the number of matters referred to the Complaints Committee and the manner in which they were dealt with:—Complaints lodged or specific transactions referred to the committee, 607; profiteering found to exist, 73; number of prosecutions undertaken, 24; number of convictions obtained before the magistrates, 17; fines imposed, £815; costs ordered, £205.

The Committee on Trusts was charged with the duty of obtaining such information as is specified in Section 3 of the Profiteering Act, 1919, which required the Board of Trade to "obtain from all available sources information as to the nature, extent, and development of trusts, companies, firms, combinations, agreements and arrangements connected with mining, manufactures, trade, commerce, finance, or transport, having for their purpose or effect the regulation of the prices or output of commodities or services produced or rendered in the United Kingdom or imported into the United Kingdom, or the delimitation of markets in respect thereof, or the regulation of transport rates and services, in so far as they tend to the creation of monopolies or to the restraint of trade."

This section embodied a recommendation of the departmental committee appointed by the Minister of Reconstruction "in view of the probable extension of trade organizations and combinations, to consider and report what action, if any, may be necessary to safeguard the public interest," which reported in 1919. It is to be noted that the Act gave no power under which any coercion could be exercised on a trade combination except in so far as it brought itself within the penal clauses of the Act by charging unreasonably high prices. Parliament appears to have taken the view that powers of this kind ought to be the subject of further permanent legislation, and that the temporary powers of enquiry and publication given by the Profiteering Act should make it possible by preliminary investigation to get together a body of facts which would be of great value when permanent legislation on the question of trade monopolies was introduced. The numerous reports by sub-committees of the Committee on Trusts constitute in fact such a body of information. They show, on the one hand, that many of the big combinations now existing have been of public benefit; that by economies in working and efficient organization of manufacture, buying, and selling, they have been able to keep prices at a lower level than they must otherwise have attained. On the other hand, instances of abuse of monopoly power have been brought to light, and, in general, many of the reports are in favour of the provision of some kind of statutory power, under which action could be taken if a strong and close organization controlling the whole or nearly the whole of an essential trade or industry adopted a policy contrary to the public interest.

The following is a list of the investigations on which reports by the Committee on Trusts have been published as Parliamentary papers:—dyes and dyestuffs, dyeing, finishing, bleaching and printing, electric cables, electric lamps, explosives, farriery, fish, fixed retail prices, fruit, glassware, iron and steel products, laundry prices, meat, milk, oil and fats, pipes and castings, road transport rates, salt, sewing cotton, soap, tobacco, uniform clothing, vinegar and yeast.

¹ Originally by the Complaints Committee, but under the amended regulations of Aug. 7 1920 by the Chairman of Central Committee.

Reports on the following subjects by sub-committees jointly appointed by the standing committees on Prices and Trusts have also been published:—bricks, cement and mortar, dyeing and cleaning, light castings, stone and clayware, slates and roofing materials, and timber.

The Profiteering Act was to remain in force for six months only. It was, however, continued for a further three months by the Profiteering (Continuance) Act, 1919, and again for a further twelve months (until May 19 1921) by the Profiteering (Amendment) Act, 1920. The Amendment Act was largely concerned with improvements of machinery in points of detail where experience of actual working had disclosed defects. It contained, however, in Section 1 an important new provision, the object of which was to encourage the various trades and industries to take into their own hands the business of checking profiteering.

Section 1 reads as follows:—

(1). Where any persons or associations of persons appearing to the Board of Trade to represent a substantial proportion of the persons engaged in the production or distribution of any article or class of articles to which the Profiteering Act, 1919 (hereinafter referred to as 'the principal Act'), is applied, submit to the Board of Trade a scheme limiting the profit to be allowed on the manufacture or distribution of the article or class of articles at all or any stages of manufacture or distribution, the Board of Trade may, if they think it expedient, approve the scheme, and, where any such scheme is so approved, any profit sought or obtained in connexion with the sale of any article to which the scheme relates, which does not exceed such profit as is allowed by or under the scheme, shall not be deemed unreasonable for the purposes of section one of the principal Act.

(2). If the Board of Trade are satisfied that any scheme so approved secures an adequate supply to the home market of any articles or classes of articles to which the principal Act is applied, the Board of Trade may by order exempt producers who comply with the scheme from any general investigation under section one, subsection (1) (a) of the principal Act in respect of those articles or classes of articles and any articles of a similar description.

The preliminary work of investigation and negotiation in connexion with schemes submitted under this section was undertaken by the Central Committee, the final approval or disapproval resting, of course, with the Board of Trade. Owing to the unexpectedly rapid fall of markets and alteration in the general trade outlook in the latter part of the year 1920, conditions were not very favourable for profit-limiting schemes. Very few were put forward; of these some were withdrawn or not proceeded with, and only two¹ (relating to men's ready-made and made-to-measure clothing and to the retail sale of coal in the London area) were actually approved by the Board of Trade.

The foregoing is a brief review of the principles on which the Profiteering Acts were based, the machinery by which they were worked, and the nature of the work. The Acts were denounced as harassing the small retail trader while enabling the profiteer on a large scale to escape; but complaints against the harassing nature of the Acts came from all quarters, wholesaler, retailer, and manufacturer alike. Although it is possible that investigations may in rare cases have caused hardship to particular interests, this can hardly be held to outweigh the valuable results in helping to dispel misconceptions and suspicions by publishing facts. The figures already quoted with regard to complaints would indeed seem a sufficient answer to the charge that trade was unduly harassed. On the other hand the deterrent effect of the Acts must not be overlooked. From the point of view of checking profiteering, the mere existence of the penal clauses of the Acts and of the machinery for their enforcement was undoubtedly of great value. As regards the absence of any definite standard of a reasonable rate of profit, the original Profiteering bill was criticized in Parliament on the ground that it gave no clear definition of the offence. This criticism was met to some extent by the proviso that a rate of profit not exceeding the pre-war rate should not be deemed unreasonable; and in the Amendment Act the position was further defined by making it clear that the standard of comparison to be aimed at was the percentage rate of net profit, not gross profit, thus

¹ Reports on these by joint sub-committees of the Standing Committees on Prices and Trusts, and also on the working of the standard boot and shoe scheme (which was not technically a scheme under Section 1), have been published as Parliamentary papers.

PROFITEERING

ensuring that the seller should not benefit unduly by the fact that his oncost or establishment charges showed a smaller increase than did cost of wages and raw materials.

A word may be added with regard to anti-profiteering legislation outside the United Kingdom. The majority of European countries, including Belgium, France, Germany, Italy, Norway, Poland, Portugal, Rumania and Sweden, passed some form of legislation with a view to checking profiteering or speculation in the necessities of life. Legislation with this object was also passed in Australia, Canada, New Zealand, the Union of South Africa, and a number of the smaller British possessions. A number of foreign countries or British possessions studied through their representatives the working of the Profiteering Acts, 1919 and 1920, and several (as for example Italy, South Africa, Gibraltar and Sierra Leone) availed themselves largely of English experience in framing their anti-profiteering legislation. (E. R. E.)

UNITED STATES

"Profiteering," as the term has been used in the United States, may be roughly defined as consciously taking and retaining profits considerably in excess of the return necessary to equilibrate demand and supply, especially when such profits are the result of prices enhanced by the activity or policy of the recipient. Its meaning has therefore a direct relation to the current conception of a legitimate business "profit"—a point on which public opinion during the World War became peculiarly sensitive. Probably, conscious direct control of industrial processes never reached such development in the United States as during the World War. Prices were fixed and both supply and demand controlled. Income taxes were highly developed. An unusual mass of information concerning cost, production, consumption and stocks was obtained. As a result much became known of the profits made in different industries, and much information concerning them was given out—sometimes with the purpose of exercising a check. In the United States the chief sources of information are the cost reports of the Federal Trade Commission and data compiled from the income-tax returns. If it be remembered that not all that seems excessive is profiteering, it will be of value to recapitulate some of these data.

According to income-tax returns from some 7,000 corporations their net earnings of the pre-war years 1911-3 averaged 11% on invested capital. This corresponds well with the common judgment at that time that from 10% to 12% (depending on the risk) was a fair profit in most industries. Unfortunately, returns are not available in published material for these same corporations in 1917, but for 1918—a year of lower profits—they averaged 15%. The year 1917 was the time of maximum profits. We know that in that year the total net income of 31,500 corporations was well in excess of the total for all corporations in the country in 1913. These corporations made an average net return on investment of approximately 22%, and more than one-half of their net income was reported by those earning 30% or more. (It is to be noted that these figures do not include corporations earning under 15%. Nevertheless, it is probable that all corporations averaged approximately 18%.)

These income-tax returns are not conclusive. The padding of investment account and of costs was all too common, and the statistical treatment of the returns is not satisfactory. They do indicate, however, that average profits increased considerably between the pre-war period and 1918. More accurate and illuminating figures concerning particular industries were obtained by the Federal Trade Commission, and a few representative cases will give the best understanding of the situation. A study of the costs of 37 wheat-flour companies showed that the average earned on investment was 12.6% in the fiscal year 1913-4, 17% in 1914-5, 38.4% in 1916-7, and 34% in 1917-8. That this increase in profits was not due solely to increase in business is evident from the fact that the percentage earned on sales also increased, the rate being 3.4% in 1913-4 and 6.5% in 1916-7. In 1917 there was apparently no limit to the price purchasers were willing to pay, the condition being one of panic. The large

profits of the year were partly due to the enhanced value of unsold stocks and to speculative profits derived from feed. In the next year profits were somewhat abated by Government regulation. The Federal Trade Commission, after noting that the margin of 25 cents per bar. allowed by the Food Administration was larger than the normal profit, said: "The Commission's investigations of costs and profits for recent months indicate that 25 cents a barrel is being taken by many millers as a guaranteed net profit after paying all income and excess profit taxes. . . ." In other words (1) taxes payable on net income were being wrongfully treated as expense, and (2) a maximum margin was being made the minimum. This course involved some fraud and showed concerted action. Depreciation and salary accounts were padded and capital charges were treated as operating expenses.

Twenty-two manufacturers of farm implements made at this time about 85% of the product in the United States. Their profits increased from about 9% on investment in the years just prior to the war to 16.6% in 1917 and 19.9% in 1918; and the rate of profit on sales increased several fold. There was no general shortage of farm implements and no unusual demand, for exports were cut off. The Commission says: "The large increase in the prices and profits of manufacturers in 1917 and 1918 was due in part to price understanding or agreements . . . and, to a more limited extent, the profits of dealers seem to have been due to similar activities."

From Senate Document No. 248 (65 Cong. 2d Session) further evidence of profiteering may be gained. It appears that oil companies circulated reports that the supply of gasoline was dangerously short, for the purpose of maintaining prices of that commodity while making "enormous" profits on fuel oil. Concerns bottling or canning vegetables, which had made future contracts, sometimes withheld portions of their output from delivery on such contracts and sold in the higher "spot" markets. In frequent cases licences were revoked by the Food Administration. The practice of such concerns in maintaining re-sale prices for jobbers contributed toward maintaining the general high level of prices and increased profits in some instances. According to the same document the steel companies in 1917, prior to Government price-fixing, made abnormal profits, and a number continued to make unusually heavy profits thereafter. The United States Steel Corp., which made 5% before the war, received 25% on investment in 1917; and 10 smaller concerns, such as begin their operations with the employment of steel furnaces, made from 30% to 319% on their investments. Certain sulphur companies took advantage of the war demand for sulphur to raise their prices to such an extent as to reap net profits of approximately \$15 a ton, which meant over 200% on investment in one case. It further appears that "unnecessarily" large profits were made by the producers of yellow pine lumber in the South. A good margin per 1,000 bd. ft. had been considered to be \$3, but in 1917 the average margin was over \$4.80; and while the average profit on investment in 1916 was 5.2%, the figure was increased to 17% in 1917. The profits of tanners increased from two to five times, as they took advantage of the enormous demand for leather and exacted very high prices. The price of hides was rapidly advanced, notwithstanding that at the same time "great supplies were withheld from the public." Upon learning of approaching price control, one of the large packers took steps "quietly and promptly" to increase the appraised value of his tanneries.

Other figures indicating the general trend may be given as follows:—

	Percentage of net earnings to Investment		
	1914	1916	1917
Meat packers (large) . . .	8.3	18.5	26.5
Tanners	12.9	33.8	25.7
Shoe manufacturers . . .	15.1	26.1	24.7
Bituminous coal (Pa.) . .	—	6.0*	32.0*
Vegetable canners . . .	—	9.0	32.0
Salmon canners	—	22.0	52.7
Petroleum refiners . . .	15.0	—	21.0
Copper producers	11.7	—	24.4

*Percentage of net sales.

According to the annual report of the Attorney-General for 1920, since Oct. 1919 sentences had been imposed on 49 sugar dealers and 20 clothing dealers. This was under the anti-profiteering law, referred to below. In addition, six sugar dealers and one flour dealer had been convicted of hoarding, and two coal dealers had been sentenced under the provision as to fixing reasonable prices. In all there had been over 2,000 indictments, arrests and sentences, involving chiefly the commodities just mentioned, together with meats, potatoes, and meals at restaurants. The great majority could not be sustained under the law.

Without further evidence it may be concluded that profits in many industries increased in the earlier part of the war more than 100% above the pre-war level, and that this increase was in not a few cases due in part to profiteering as above defined. High prices do not necessarily indicate excessive profits, but there is reason to believe that profiteering was common in cement, petroleum, lumber (notably ship timber), wool, clothing, sulphur, naval stores, rice, sugar, sand and gravel, raisins and other products, in addition to those already mentioned. In most of these cases the Government reduced prices and profits through some form of control. Anyone who had experience at Washington during the war knows that many persons went there for the purpose of furthering profiteering schemes. In some cases the method was to secure contracts at excessive prices, perhaps by bribery, certainly by misrepresentation. Many such cases later came to light, some concerning articles of clothing for the army and involving collusion with army officers. In other cases the method was to induce the Government to abstain from fixing a reasonable price or to induce it to fix a high price. Thus, in the United States, oil companies succeeded in virtually preventing any price-fixing on the ground that the exorbitant prices that prevailed were necessary to stimulate production; while lumber, copper and cement associations by concerted and persistent activity obtained prices that were unnecessarily high. In still other cases every effort had been made to defraud the Government in respect of excess profits taxes, to enable a business to "retain" profits larger than lawful. Equally reprehensible was the action of hosts of retail dealers, such as those selling shoes and men's clothing, who maintained the same percentages of profits on sales although the great increase in prices meant greatly increased absolute margins and percentages on investments.

The U.S. Government attempted to deal with profiteering in three ways: (1) taxation; (2) price-fixing; (3) direct action under the Food Control Act. The first and the last methods proved largely ineffective.

By special taxes levied on profits, many thought that the spoils of the profiteers could be regained by the public. In 1916 a tax of 12½% was levied on the profits of munitions manufacturers; and a general "war profits tax" and an "excess profits tax" were imposed in 1917. In 1918 these taxes were combined. Under this measure profits of corporations organized for profits were liable either to (1) a progressive tax on profits in excess of 8% on capital; or to (2) a flat tax of 80% of net income over the average profits for the three pre-war years 1912, 1913 and 1913. Not a few legislators and economists hoped that these taxes would make regulation of prices or profits unnecessary. Let any concern make what it can, they said, we will take it as fast as they make it. But, unfortunately, it proved so easy for most corporations to increase their investment accounts, and to pad their expenses, that the worst profiteers often showed small excess profits. Moreover, a considerable part of the tax was shifted to consumers in the shape of higher prices, as was possible during the inflation period.

Government price-fixing, while it did not prevent profiteering, did moderate the evil, notably through such substantial reductions as were made in the prices of wool, coal, sugar, flour and sulphuric acid. Unfortunately, this means was not used as vigorously and thoroughly as it would have been had there not been an ill-founded reliance upon profits taxes.

On Aug. 10 1917 the Food Control Act became law. Section 4 of this Act made it unlawful for any person to hoard or to make any unjust or unreasonable charge in transactions relating to

"necessaries" (foods, feeds, fuel, fertilizers, farm implements and machinery), but imposed no penalty. Sections 6 and 7, however, provided for penalties and seizure, in case of hoarding. Section 3 authorized the licensing of dealers in necessities and the fixing of fair storage charges, commissions, profits, or practices. The fixing of prices for coal and coke was authorized in section 25. It was under this Act that the Food Administration operated, and, as already indicated, its control over prices was partly effective. On June 30 1919, however, the activities of the Food Administration were suspended; and as the agitation concerning the "high cost of living" grew in volume, the Department of Justice assumed the task of enforcing the law, which remained in force while a state of war was only technically in existence. Between Aug. and Nov. 1919, the Department made some 92 seizures of such food products as eggs, butter, sugar, flour and pork, under section 7, and secured several indictments under section 6, one indicted party pleading guilty. The chief agencies depended upon were the local "fair price committees" such as had been established under the Food Administration. Indeed, the wartime organization of local food administrators was partly revived, and an extensive publicity campaign was initiated. But the Attorney-General found his efforts hampered by the absence of a penalty clause in section 4 and the restricted definition of "necessaries," and, at the President's request, Congress reenacted the law in Oct. 1919, with amendments to cover these defects. Encouraged by this action, and animated, it is charged by his critics, largely by political ambition, the Attorney-General proceeded vigorously under the Act, and in his annual report for 1920 stated that there had been 1,049 prosecutions under section 4 and 99 convictions.

Meanwhile, a growing hostility to the Act was apparent, and the courts in several jurisdictions declared it unconstitutional. This was true in five of the ten chief bituminous coal-producing states. Action concerning anthracite coal profiteering was also blocked by a decision of the Federal District Court in Pennsylvania. The upshot of the matter was a decision of the Supreme Court in Feb. 1921, which finally declared the Act unconstitutional. The case was that of *U.S. v. L. Cohen Grocery Co.*, and involved profiteering in sugar. The reasoning of the Court was that Congress alone had power to define crimes against the United States; and, therefore, because the Act was vague and indefinite, and fixed no precise standard of guilt, and because it did not inform the defendant of the nature and cause of the accusation against him, it was unconstitutional. Thus ended the anti-profiteering crusade of the Attorney-General. Meanwhile, from April 1920 prices began to decline, and with that decline came a loss of interest in profiteering.

In a sense the U.S. Government was to blame for much wartime profiteering. In the first place it was lax in letting contracts and making purchases, either directly, or indirectly, by placing authority in the hands of interested persons. The "cost-plus system" invited profiteering as well as inefficiency. In the second place its combination of excess profits taxes and price regulation was unfortunate. At the same time that it fixed prices on a cost basis it spread the idea that it made little difference if excess profits were earned, as such profits would be reached by taxation. Taxation, however, proved at best to be an inadequate means of reaching profits, and early laxity in defining cost and investment made this means nugatory. The system as it worked in the United States tended toward laxity both in fixing prices and in collecting taxes on income. (L. H. H.)

PROFIT-SHARING AND CO-PARTNERSHIP (see 22423).

Profit-sharing was defined by the International Conference on Profit-Sharing held in Paris in 1889 in the following formula:

"The International Congress is of opinion that the agreement, freely entered into, by which the employee receives a share, fixed in advance, of the profits, is in harmony with equity and with the essential principles underlying all legislation." This definition, which is accepted by nearly all writers on profit-sharing, excludes on the one hand distributions made by a firm to its employees, say at Christmas, the amount of which is not fixed in advance, and to which the employees have no definite right.

such distributions are to industry what the Squire's coal and lankets are to village life, but they are not profit-sharing. It so excludes forms of "output bonus," etc., under which the individual employee (or the squad or gang) gets, or is supposed to get, a share of the money which he individually saves to the firm by working faster or better; this was formerly classed with it under the general term *gain-sharing*, and *profit-sharing* still sometimes incorrectly used to cover such forms of bonus. Under true profit-sharing the share of the employees varies with the prosperity of the firm, and depends therefore not on their exertions solely but on the competence of managers and directors, the state of the market, and other considerations.

The Labour Co-Partnership Association in 1911 expressed its view that the co-partnership of labour with capital involved: (1) "That the worker should receive, in addition to the standard wages of the trade, some share in the final profits of the business, or the economy of production. (2) That the worker should accumulate his share of the profits, or part thereof in the capital of the business employing him, thus gaining the ordinary rights and responsibilities of a shareholder." To this in 1910 the Association added a further clause: (3) "That the worker shall acquire some share in the control of the business the two following ways:—(a) By acquiring share capital, and thus gaining the ordinary rights and responsibilities of a shareholder. (b) By the formation of a co-partnership committee of workers having a voice in the internal management." The adoption of the last clause is due to the belief, now rapidly gaining credence, that the smaller shareholders in the ordinary firm have in reality little or no voice in its management, and that other means are necessary to provide the employee co-partners with their share in control. It has not, however, been adopted by, or nearly all, of the firms which have co-partnership schemes. Profit-sharing and co-partnership are thus seen to differ in origin by the fact that the profit-sharer has a share only in the profits of his employer over a given period, and may take his share away in his pocket entire, whereas the co-partner must have some of his profit in the form of investment in the business, and receives also some share in the management. In some cases the co-partner does not actually have to invest, but is offered shares at par or at reduced rates, or even free, these shares usually carrying with them all shareholders' rights. In practice, however, there are so many possible variations that no general distinction is possible, and the terms are frequently interchanged. It will also be observed that both forms assume the existence in industry of two parties, the "firm" and its employees. They are therefore not connected with the various coöperative experiments which have been made from time to time by groups of workers, forming themselves into a union and dividing amongst themselves the profits or losses, such as the coöperative colonies of Robert Owen in England, or the *ateliers* or self-governing workshops of Louis Blanc in France. Co-partnership, as now understood, is distinctly a "paternal" movement, the dominant "partner" in industry being moved to confer a favour on its junior; and though the ideals of Owen, Fourier and the Christian Socialists may have had some influence on the minds of the earliest co-partners, a truer descendant than co-partnership of to-day is the working-class Coöperative movement, which aims at the supersession of capitalism.

The earliest example of co-partnership comes from France. In 1843 a master painter of Paris, Edmé-Jean Leclaire, divided among his permanent hands (43 out of about 300 employed) the sum of 22,266 francs. The scheme met with approval and in 1870 this "kernel," as he called it, of permanent workmen, who were members of the firm's mutual provident society, continued to take their share of the increasing profits. At no time did the members of the mutual provident society amount to more than a third of those employed. In 1870 the profit-sharing was extended to all the men employed, for however short a time, and upon this basis it has continued as "Brugnot, fils et Cie. (ancienne maison Leclaire)." The arrangement for division of profits is as follows:—5% is first paid on the total; of the remainder 15% goes to the managing partners

(who according to French law have unlimited liability), 50% as a dividend to all workers in proportion to their time wages, and 35% to the mutual provident society—the "kernel"—which is now a partner in the business. The managing partners also receive a salary. This experiment, as it was the first, is also peculiar in the amount of control entrusted to the permanent workmen, the "kernel," who are very carefully chosen. Among their other privileges it falls to them to elect new managing directors among the employees, a privilege not, as far as the writer is aware, granted under any English scheme of co-partnership. The whole business, however, employs only between one and two thousand workers; its interest is, therefore, chiefly as an experiment. (For fuller accounts of this and other French schemes, including the *Familistère* of Guise, consult the publications mentioned at the end of this article.)

France, as it was the original home of co-partnership, has also been the country in which it has excited the most interest, and the comparative lack of trustification in French industry has made it easier for schemes established by individual firms to be accepted. The numerical weakness of French trade unionism has also made it easier to gain the adherence of French workers, for an established trade-union movement is generally hostile to co-partnership and profit-sharing.

United Kingdom.—In the British Isles, if we except a scheme inaugurated in 1829 by Lord Wallscourt for the farmers on his Galway estates and abandoned shortly afterwards, the movement begins in 1865 with the adoption of six schemes, of which five have since been abandoned, although one (adopted by Messrs. Jolly & Son, silk mercers, of Bath) survived until 1906. One of the five was the famous Briggs scheme, of the Whitwood and Methley Collieries, to which reference is made below. The movement then progressed very slowly for some years. Between 1865 and 1888 only 66 schemes in all were launched, of which all but fourteen had disappeared by 1920.

The International Congress on Profit-Sharing which drew up the definition quoted at the head of this article was held in 1889. In that year also the South Metropolitan Gas Co. adopted profit-sharing, and thus initiated it in the only British industry in which it has obtained any considerable hold. These two facts combined to stimulate an interest in profit-sharing, and during the four years 1889-92, 83 schemes were adopted, of which only 12 survive. A long decline in profit-sharing, owing partly no doubt to the trade depression which began in 1892, led up to rather less vigorous revivals during 1908-10 and 1912-4. The World War then practically put an end to the development of the system, until the phenomenal profits of the early months of the peace and the willingness of many firms to share some of them with their employees, led to an outburst of 42 schemes in 1910. The boom continued during the early months of 1920 (19 during the first six months); but during the subsequent industrial depression there was a marked slackening of interest in this direction.

Up to the end of 1919 the British Isles had given birth to 417 schemes, of which 108, or slightly less than half, have been abandoned for one cause or another. Of the remainder, 36 were run by gas companies (*see* below). These figures alone, however, would give a misleading impression of the size of the movement. Of the 144 schemes started up to 1918, only 15 are returned as affecting more than a thousand employees, while no fewer than 54 affect less than a hundred. Out of the 15 again, four are run by gas companies (the South Metropolitan, the South Suburban, the Gas Light and Coke Co., and the Liverpool Gas Co.), and of the remaining 11, four of the largest affect only a portion of the workpeople in the firm's employ. These are:—Messrs. Armstrong Whitworth & Co., (12,215 out of 69,000 employed); Messrs. Pease and Partners, of Darlington (2,243 out of 11,000); Messrs. Lever Bros. (3,542 out of 8,833); and the Bradford Dyers' Assn. (3,600 out of 9,800). The only really large concern whose profit-sharing affects nearly the whole of its workpeople is the Prudential Assurance Co., 18,500 of whose 20,000 employees participate in its scheme. Details of the number participating are not available for schemes

started since 1918, but as out of the 42 firms only eight have a pay-roll of over 1,000, while ten employ less than 100, it would seem that the proportions would not be materially altered if they were all included. Neither do all the smaller firms include by any means all their employees in their profit-sharing schemes. The proportion varies from case to case, falling as low, in the case of one firm of manufacturers, whose scheme dates from 1880, as 50 out of 1,500, or 3½ per cent. It is clear that in this and similar cases the co-partnership is really a tiny experiment carried on with a few picked employees and is of infinitesimal significance in the industrial life of the country. Nor is it only the successful experiments that are of this type; the abandoned schemes tell the same tale, except that the number of participants is lower.

Apart from the gas companies, then, co-partnership in British industry has been confined, with one or two exceptions, to small firms, and these for the most part in minor industries. The food trades, such as cocoa, confectionery, jam, chocolate, etc., and the distributive houses provide a large number of experiments; tailoring, dress-making, boot and shoe manufacture, and printing and stationery are also considerable groups. In the great basic industries of the country, (mining, cotton, engineering and shipbuilding) and in transport, co-partnership has made practically no progress, nor does it seem to be making any.

What is the reason of this? An analysis of the reasons given for the abandonment of dead schemes may provide part of the answer. Forty-nine schemes were abandoned "for financial reasons," i.e. because there had ceased to be any profit to be shared. In 16 cases no cause can be assigned; and in about 40 the abandonment was due to changes connected with administration. There remain 91 schemes which were abandoned owing to the dissatisfaction of owners or men with their results. The men's dissatisfaction can generally be traced to a simple cause—the smallness of the dividend distributed. The average rate of bonus paid to workmen under all schemes varies within narrow limits and is generally about 5% per annum on the total of their wages. Translated into cash, this meant in 1918 that 105 firms paid to their workmen an average of £3 13s. 3d. per head, or, if the firms which paid nothing at all be excluded, of £5 15s. 2d. In 1910, the average bonus paid per head was £4 18s. 10d. It will readily be understood that so exiguous a cash benefit causes considerable disappointment to the worker who has been led to expect material advantages from being provided with an interest in the business; and this fact may also go some way towards explaining the failure of schemes which employers gave up owing to the "apathy" of their workmen. £3 13s. 3d. per annum, especially when paid in a lump at the end of twelve months, during which the workers have been working at ordinary rates, is hardly likely to provide a very strong incentive to better work.

This may account for the high mortality among profit-sharing schemes which have actually come into existence. More reasons, however, are needed to explain the smallness of their numbers and their comparative insignificance. This is undoubtedly due in part to the hostility of the consuming public, which tends to regard profit-sharing schemes as designed to keep within the industry money which should be used to reduce the price to itself. Thus the distributive Coöperative Movement, which is an association of consumers, has done very little in the way of profit-sharing or co-partnership, and that little is steadily growing less, and the English and Scottish Coöperative Wholesale Societies have both abandoned their schemes of profit-sharing, the former in 1886, and the latter in 1915.

The gas companies, to which reference has already been made, are not open to this criticism owing to their peculiar statutory position. All gas companies are regulated by Act of Parliament, and in most cases they are not allowed to increase their dividends unless the price of gas is correspondingly reduced. (In the other cases the dividend is limited to a fixed maximum percentage.) Thus the gas companies have never been able to make enormous profits at the expense of their customers, and moreover, since their accounts of capital and dividend must be regularly rendered to the Government, there is little or no cause for the

suspensions which occasionally develop in co-partnership concerns, of "watered" capital and the like. Further, there was frequently before the war a considerable surplus which the companies did not wish to use in reduction of price, which, therefore, not being available for shareholders' dividend, could be distributed among the employees. This, by keeping up the workers' dividend, served to render the profit-sharing scheme popular. Since the war, surpluses have largely disappeared.

But the greatest bar to the success of the co-partnership movement has undoubtedly been the hostility of the organized labour movement. The trade unions are almost uniformly opposed to it as a policy, and in some cases even expel any member joining a co-partnership or profit-sharing scheme. This was the case in 1920 with the Amalgamated Society of Woodworkers, whose right to expel members joining Lord Leverhulme's scheme at Port Sunlight was contested in the courts, though the decision finally went against them. The earliest firms to adopt profit-sharing did little to allay the suspicions of the unions. They were generally as unfavourable to the unions as the unions were to them. The well-known experiment of Messrs. Henry Briggs & Co., which was launched in 1865, was avowedly intended to draw the men away from their union, and came to an end ten years later, after a somewhat stormy career, because the employees chose rather to uphold their union in resisting an attempt by the employers to reduce wages than to remain in the firm's employ and get what they could. The scheme of the South Metropolitan Gas Co., which nearly came to grief in its first year owing to the company's insistence that every workman should sign a yearly contract, dating from different days in each case (which would have rendered any concerted strike punishable at law), also required, until 1902, every workman to sign a declaration that he was not a member of the Gasworkers' union. Recently this attitude has been modified, and the most distinguished advocates of co-partnership, such as Mr. Aneurin Williams, now insist on the recognition of trade unions: but the unions nevertheless hold that it gives the workers in a single firm a sectional interest and so tends to divide them from their fellows in the same trade, and, further, that there is always a danger that workers in a profit-sharing firm may, in return for the profit-sharing, be induced to accept less than the rates of wages which it is the unions' business to maintain. As far as one can see, this attitude is not likely to be easily changed in the near future, and the co-partnership movement, therefore, is unlikely to spread beyond the small firms and the minor industries in which trade unionism is weak.

BIBLIOGRAPHY.—The Ministry of Labour's *Report on Profit-Sharing and Labour Co-Partnership in the United Kingdom* (Cmd. 544, 1920) is indispensable. It contains nearly all the available information, and has an exhaustive bibliography. The best book giving the case for co-partnership is Charles Carpenter's *Industrial Co-partnership*. A useful book is *Co-partnership and Profit-Sharing*, by Aneurin Williams (Williams and Norgate, 1913); a good analysis is to be found in *Methods of Industrial Remuneration*, by D. F. Schoss (Williams and Norgate, 1907). Later Edition. The Labour Co-partnership Association, 6, Bloomsbury Square, London, W.C.1., published a number of brochures dealing with particular aspects and particular experiments.

For the Labour point of view the best works are two pamphlets by Edward R. Pease: *Profit-Sharing and Co-Partnership; A Fraud and a Failure?* (Fabian Soc., 1913) and *Co-Partnership and Profit-Sharing* (Labour Party, 1921). See also chapters in *The World of Labour*, by G. D. H. Cole.

United States.—Profit-sharing, strictly defined, is a plan for increasing the ordinary remuneration of labour by amounts varying with the profits of the business. Popularly, the term is loosely used to describe a great variety of methods of wage payment. In this article it is used to describe an arrangement by which employees, other than managerial employees, receive, in addition to wages or salaries, a share of the net profits of the business, such share being distributed at the time of the declaration of dividends to stockholders. The arrangement may be expressed either by a formal agreement or an oral promise. Although the profits are contingent, the percentage of profits to be distributed is fixed and known in advance, and, like dividends,

is paid sometimes in whole or in part in stock instead of cash. This definition excludes many forms of wage payment commonly associated and confused with profit-sharing, such as the bonuses sometimes measured by individual or collective output, length of service, attendance at work or employee savings, and sometimes given as Christmas gratuities, and such as sundry stock-purchasing schemes, none of which fluctuate directly with the net profits.

The term "co-partnership" is not generally used in the United States in this connexion, since the implied constituents, profit-sharing, stock-ownership and participation in management, are not often found in the same establishment. Many profit-sharing plans arrange for distribution of stock as a part of, or as an addition to, profit-sharing. There are also more than 60 known stock-purchasing schemes, besides many arrangements for "managerial" or "limited" profit-sharing, affecting less than one-third of the total employees. Probably fewer than ten of these varied plans provide for workers' committees as an integral part of the arrangement.

Related to the idea of co-partnership, but quite apart from profit-sharing, are a considerable number of schemes for labour's participation in management which have sprung up during and since the World War. These schemes vary all the way from representation on boards of directors, in a very few cases, to joint management through industrial and works councils, shop committees, grievance and welfare committees, shop chairmen and voluntary arbitration boards. The distinguishing characteristic of these management-sharing plans is that under them the management does not depend upon organized labour, but deals with its own employees collectively. They are distinct from profit-sharing, in that the employer retains all of the profits he makes, though the workers are given collectively a voice in determining the wages, hours and working conditions which to some extent affect the profits account. Without doubt labour's participation in management in such a sense is more usual than profit-sharing and co-partnership.

The pioneers of true profit-sharing in the United States, dating from 1886, are the Ballard and Ballard Co. of Louisville, Ky., engaged in flour-milling, and the N. O. Nelson Manufacturing Co. of St. Louis, Mo., manufacturers of plumbers' and steam-fitters' supplies. The years of greatest installation of new projects were 1901, 1906, 1909-11, 1914-6, and 1919. Fully 70% of all the known plans were started after 1910. These variations in the progress of profit-sharing in the United States correspond with those in England, where profit-sharing plans found favour during periods of ample employment and labour unrest. It is only natural, however, that periods of low profits should check the spread of profit-sharing and cause the abandonment of many plans, the average life of abandoned plans being two to three years. For this reason, and since no comprehensive study had been made in the five years preceding 1921, it is difficult to state with confidence the exact number of profit-sharing arrangements existing in that year, one of general business depression. On the basis of the Government report in 1916 and subsequent semi-official studies it is estimated that 86 true profit-sharing plans were in operation at the end of 1920. Of these plans more than one-half (53%) were in manufacturing establishments, 16% in mercantile concerns, 11% in banking institutions, 9% in public utilities and the remainder scattered. Approximately two-thirds of these concerns employed less than 300 people, and only one-seventh employed more than 1,000, so that the total number of employees was less than 50,000. The number of arrangements solely for stock purchasing is not accurately known but the inclusion of several large corporations, as the United States Steel Corp. and the International Harvester Co., raises the number of participating employees to a million or more.

In the determination of the divisible fund of profits, two general methods, subject to individual variations, are followed: (1) Setting aside a specific percentage of profits after all ordinary expenses of the business, such as depreciation reserves and interest on invested capital, are taken care of; (2) fixing a rate of dividend on employees' earnings coördinate with the rate of

dividend on capital. Assume a corporation capitalized at \$1,000,000 with an annual payroll of \$100,000 and net profits of \$200,000 a year. In most plans using the first method, the preferred and common stockholders first receive dividends (not to exceed a certain per cent, say 10%, or \$100,000). The remainder of the profits fund (\$100,000) is divisible and is shared with labour according to a fixed percentage, perhaps 50% to labour and 50% to capital, or 40% to labour and 60% to capital. Four of the more recent plans allow employee beneficiaries to send an accountant on their behalf to verify the company's computations. Under the second method, the divisible fund depends on dividends declared. Thus if a 10% dividend is declared, a fund equal to 5% or 7½% of the total payroll (\$5,000 or \$7,500) is distributed among workers. The advantage to the management of this method is that it may be found desirable to pass all dividends and use this amount for strengthening the business.

When the amount of divisible profits has been determined, there remains the apportionment of the respective shares to capital and labour. In most instances the employer determines this apportionment at the outset, announcing that perhaps 50% or 40% or 33⅓% of the divisible profits will be distributed among employees according to their earnings. Often, however, divisible profits are distributed according to the ratio of (1) total invested capital to total payroll or (2) interest on invested capital to total payroll. Assuming, in the example given above, that \$120,000 remains to be divided, the ratio in the first instance is \$1,000,000 (capital) to \$100,000 (payroll) or ten to one, which allots \$10,000 to labour and \$100,000 to capital. In the second case, assuming 6% as a fair return on the investment, the ratio is \$60,000 (interest) to \$100,000 (payroll) or six-tenths to one, in which event labour's share is \$75,000 and capital's share is \$45,000. This latter method of division in 1921 was known to obtain in only one establishment.

An almost universal rule is that length of service shall be a condition of the eligibility of participants. In one or two cases the employee benefits as soon as hired. But most schemes require from three months to three years of continuous employment as qualification for a share in profits. Concessions from the specification of "continuous" employment are sometimes made to provide for such contingencies as sickness, unavoidable lay-off and accidents. Discharge for cause or quitting employment entails an automatic forfeiture of all claims to accumulated or accruing shares in profits; in one plan discharge for cause is the only occasion for forfeiture. The obvious intent of such regulations is to reduce labour turnover by rewarding the faithful. In this respect profit-sharing indirectly acts as a length-of-service bonus. A further rule as to eligibility in some plans is to require a written application from the employee who wishes to participate. In one such case employees are obligated to share in possible losses, not to exceed 10% of their earnings, 10% of their pay being held back by the employer each week to provide for this contingency. Loss-sharing in addition to profit-sharing is incorporated in four schemes. Still another restriction is as to the class of work performed, as shown by the amount of salary or wages or by classification of employment. Firms using this restriction evidently feel that the type of their workmen is such that only a sharing limited to some of their employees would produce the desired results. Yet there is also the wish to experiment fully and the desire to extend the benefits of the plan, should limited participation be successful.

The form and time of payment of shares to employees are also important variants. Over three-fourths of the firms studied in 1916 paid their shares fully in cash, annually, semi-annually or quarterly. The others paid part in cash, part in company stock, or paid part into a common welfare fund or savings account. The stock-sharing or co-partnership plans provided many restrictions designed to encourage thrift, and to discourage speculation and absentee ownership. These restrictions take the form of prohibitions of sale of stock, sometimes only with the consent of an official of the company, or holding the stock in trust for the employee and paying him only the dividends, or of forfeiture of participating rights if such stock be sold.

Four plans provide for workers' co-partnership committees, though there are several strictly stock-purchasing plans which allow shareholding employees to acquire a voice in management through the exercise of the ordinary voting rights of shareholders. The extent of the co-partnership in these forms is negligible.

All these varying details (and the variations are by no means exhausted in this recapitulation) reveal in large measure the spirit and purpose of profit-sharing. As a rule the employer announces his plan without previously consulting his employees. There is virtually unanimous agreement among successful profit-sharing employers that the coöperation, loyalty and stability of working forces—the chief avowed purposes of profit-sharing—are obtained by all the plans which have been in operation for any considerable period. There are, however, varying opinions as to how far these plans attain the more specific objects of (1) economy of time and material, (2) improvements in quality and quantity of output, (3) inducement to thrift, (4) avoidance of industrial disputes, (5) attainment of social justice. On the whole there is a considerable body of employers' opinion supporting the value and practicability of profit-sharing in improving industrial relations.

On the other hand union leaders universally condemn profit-sharing for three general reasons: (1) Where profit-sharing exists, wages less than the market rates are paid; (2) workers prefer a fair, fixed wage scale rather than a part of their wages undetermined and subject wholly to the employer's decision; (3) labour organization is undermined, as obligations to the firm are made a first lien on the workers' loyalty. That these criticisms have some foundation in fact is proved by the high percentage of abandoned plans and the reasons for their failure. Most of the failures were due to apathy or open hostility on the part of the workers, expressed in strikes, to diminished profits, or to changes in ownership of the business.

The success or failure of profit-sharing plans depends on circumstances not touched by the profit-sharing principle. Where favourable results have been obtained, they were due, not to profit-sharing as a mechanical device, but to the confidence which the employees had in the management.

Bibliography.—A comprehensive bibliography will be found in Boris Eramet's report "Profit-Sharing in the United States"—United States Bureau of Labor Statistics, Bulletin No. 208, 1917. PROHIBITION.—In the earlier article (see 26.578) under **TEMPERANCE**, reference has already been made to the various methods devised for securing total abstinence from the consumption of intoxicating liquor, and in particular to the progress of the movement for legislative Prohibition in the United States up to the year 1910. This latter movement eventually culminated in the establishment of nation-wide Prohibition by the Eighteenth Amendment to the Constitution of the United States, as proposed by Congress, Dec. 3 1917, ratified by the necessary three-fourths of all the states, and officially proclaimed, Jan. 29 1919, as part of the Constitution, becoming effective, in accordance with its terms, one year from the date of ratification by 36 states, namely Jan. 16 1920.

In the separate article under **LIQUOR LAWS** the measures adopted in Great Britain for further regulating the liquor traffic during 1910 to 1921 are dealt with; and here it is only necessary to deal with the advent of complete national Prohibition in the United States, where its adoption forms one of the most interesting chapters in the social history of modern times. The movement for Prohibition was affected by new scientific knowledge, new views of industrial economics, and educational forces of great variety, considerably intensified, but not substantially changed in character, by the experience of the World War. The conviction had grown steadily in the United

States that social and industrial efficiency, and national unity of purpose, could not be had at any cheaper price than the cost or sacrifices involved (whatever they might be) in national prohibition; and this belief had almost reached the point where it could be translated into effective governmental action even before the war necessitated a supreme effort for such efficiency. Surprising evidence of this was seen in the passage, by a majority vote (193 to 189) in the House of Representatives, of the Hobson amendment for national prohibition, Dec. 22 1914, two years and four months before the United States entered the war. Save for the war, the country would probably not have had constitutional (which means virtually permanent) national prohibition as early as 1920. Forces were, however, at work which would have probably brought it within another decade, and with it the "bone dry" enforcement contemplated in the National Prohibition Act (popularly called the Volstead Act), the significant title of which is "an Act to prohibit intoxicating beverages, and to regulate the manufacture, production, use, and sale of high-proof spirits for other than beverage purposes, and to ensure an ample supply of alcohol and promote its use in scientific research and in the development of fuel, dye, and other lawful industries."

Up to the wartime legislation of 1917 and 1918 and the Volstead Act of Oct. 28 1919 for the enforcement of the Eighteenth Amendment, there had been but little change since 1910 in Federal policy. Federal taxation of liquor was greatly increased for revenue purposes in 1917 and 1918. The increasing sentiment in favour of prohibition throughout the country was reflected, however, in other Federal measures. In 1913 the Webb-Kenyon Act was passed, over President Taft's veto. It was based on the constitutional grounds that the Act delegated power over interstate commerce, exclusively vested in Congress, to a state, by making illegal the shipment of liquor from a "wet" state to a "dry" state contrary to the laws of the latter. Some such measure seemed necessary in order that local prohibition might be enforced in "dry" territory. Another indication of national sentiment in favour of restriction is found in the same year in the passage of the Jones-Works Excise Bill for the District of Columbia, which reduced the number of licensed saloons by Nov. 1 1914 to not more than 300, about half as many as before. The Isthmian Canal Commission on July 1 1913, by an administrative order previously adopted, abolished 35 saloons in the Canal Zone by declining to issue any further licences for the sale of liquor. In 1915 absolute prohibition for the District of Columbia was proposed in a rider to an appropriation bill, and defeated in the Senate by a small majority, and in the same year a bill for that purpose was favourably reported in the Senate by the Committee on the District of Columbia. In 1916 the Judiciary Committee of the Senate reported, 13 to 3, a resolution proposing the National Prohibition Amendment to the Constitution. A similar resolution received a majority vote in the House of Representatives in Dec. 1914, though it failed to secure the two-thirds necessary for passage. During the years 1915 and 1916 many of the states had enacted statewide prohibition laws, and there was a considerable extension of dry territory under local option in wet states.

Early in 1917 Congress enacted the Federal Anti-Liquor Advertising Bill with the so-called Reed Bone-Dry Amendment, as an amendment to the Post-Office appropriation bill. This was a drastic prohibition of the use of the mails for advertising, or soliciting orders for, liquor in "dry" territory, and was an extension of the principle of the Webb-Kenyon Act. Congress also adopted prohibition for the District of Columbia, over which it has exclusive legislative power. It provided for prohibition in Alaska to be effective Jan. 1 1918, and in the Porto Rican Citizenship and Civil Government Act it made provision for a referendum in Porto Rico on prohibition. This was held in July 1917, and resulted in a vote of 99,775 for prohibition to 62,195 against. All this action by Congress took place before the declaration of war in April, 1917. Following that declaration came the enactment of wartime prohibition in the Food Control Act of Aug. 10 1917, the liquor restrictions of the draft law of

PROHIBITION

May 18, and the extension of their application in the Act to promote the efficiency of the navy, approved Oct. 6 1917. These measures are discussed later in the section on wartime legislation.

Quite apart, however, from war legislation, on Aug. 1 1917 the Senate adopted the resolution proposing to the states the National Prohibition Amendment by a vote of 65 to 20—more than two-thirds of the members present, and this resolution was adopted by the House with some amendments Dec. 17 by a vote of 282 to 128. On Dec. 18 1917 the Senate concurred in the amendments made by the House, and the resolution was thereupon submitted to the Legislatures of the several states for ratification. Ratified by the last of the necessary 36 states (Jan. 16 1919), and proclaimed by the Secretary of State (Jan. 29 1919), it became the Eighteenth Amendment to the Constitution, to go into effect one year from the date of its ratification, namely on Jan. 16 1920. The wording of the Amendment is as follows:—

1. After one year from the ratification of this article the manufacture, sale or transportation of intoxicating liquors within, the importation thereof into, or the exportation thereof from the United States and all territory subject to the jurisdiction thereof for beverage purposes is hereby prohibited.

2. The Congress and the several states shall have concurrent power to enforce this article by appropriate legislation.

3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the legislatures of the several states, as provided by the Constitution, within seven years from the date of the submission hereof to the states by the Congress.

After Jan. 16 1919 the Amendment was ratified by all but three of the remaining states.

Whatever allowance may be made for the effect produced by the political activities of the Anti-Saloon League, an analysis of the vote in Congress for the submission of the Amendment

showed a fair proportionate representation of the people residing in "dry" territory, and also the proportion of "dry" to "wet" territory in the United States. The subsequent votes in the State Legislatures on ratification of the Amendment corroborate this view. The accompanying table shows the order and dates of ratification by the several states, and the vote in each House of the State Legislatures by which ratification was enacted. The total number of votes in the state Senates or upper Houses, for ratification, was 1,297 in favour and 236 against, or 84% for national prohibition to 14% against; in the lower or more popular branch of the state Legislatures, the total vote for prohibition was 3,742, or 78%, to 1,001 or 22% against. It will be noted that in South Dakota, Idaho, Washington, Kansas, Utah and Wyoming no votes were cast against ratification.

The three states which had not ratified the Eighteenth Amendment to Sept. 1921 were Connecticut, Rhode Island and New Jersey. That the ratification of the proposed amendment failed in all three states by a very narrow margin is seen from the following facts. Rhode Island's State Senate by a vote of 20 to 18 on March 2 1918 postponed indefinitely the consideration of the ratification resolution; the resolution was presented again at the 1919 session, when the Senate voted 25 to 12 to postpone indefinitely its consideration. In Connecticut the Senate voted 14 for ratification and 20 against, and the House 153 for and 96 against. In New Jersey the House passed the ratification resolution, Jan. 24 1921, by a vote of 52 to 4, but the vote in the Senate on April 7 1921 was 10 in favour to 8 against, and the resolution failed because the state Constitution required at least 11 affirmative votes in the Senate as then organized.

Following the adoption of the Amendment came the Volstead Act, which was passed over President Wilson's veto on Oct. 28 1919. Before that, however, in addition to further war legisla-

Votes in Legislatures on Ratification of Eighteenth Amendment.

	Ratified by Upper House.	Ratified by Lower House.
(1) Mississippi	Jan. 8 1918, 28 to 5	Jan. 8 1918, 93 to 3
(2) Virginia	Jan. 10 1918, 30 to 8	Jan. 11 1918, 84 to 13
(3) Kentucky	Jan. 14 1918, 28 to 6	Jan. 14 1918, 66 to 10
(4) South Carolina	Jan. 18 1918, 28 to 6	Jan. 28 1918, 66 to 29

* Repealed in Lower House to correct error Jan. 23.

tion affecting the liquor traffic, Congress enacted in 1918 prohibition for Hawaii and in 1919 a bone-dry law for the District of Columbia.

National prohibition was proclaimed Jan. 29 1919, and the year of grace allowed by the Eighteenth Amendment for it to go into effect was intended to give liquor manufacturers and dealers time in which to liquidate their business and dispose of their stocks. The so-called wartime Prohibition Act, however, which was enacted 10 days after active warfare had ceased (Nov. 21 1918), became effective on July 1 1919. The production of beer, except "near-beer," had been stopped at the beginning of the year as a food conservation measure, but even after wartime prohibition became effective, 2.75% beer was manufactured in some states on the assumption that it was a non-intoxicating liquor, and because Congress had not yet defined the quantity of alcohol a beverage might contain without coming within the meaning of the word "intoxicating," as used in the various laws, regulations and administrative orders. Rhode Island for example, enacted a state law declaring all liquors of less than 4% alcohol to be non-intoxicating.

The questions thus raised, together with the definitions of the Volstead Act declaring all liquors containing one-half of 1% of alcohol or more to be intoxicating and hence prohibited, were taken to the Supreme Court, which finally sustained both the Eighteenth Amendment and the Volstead Act's definition of intoxicating liquor, in two cases (*Hawke v. Smith* and *Rhode Island v. Palmer*, 253 U.S.) in which decision was rendered June 12 1920. The Court had previously sustained the War Prohibition Act and the one-half of 1% limit which it specified; but the liquor interests and the liquor-consuming public hoped that greater latitude would be given them by a narrower construction of the first section of the Eighteenth Amendment, which prohibited only intoxicating liquors, and therefore, it was argued, did not warrant legislation forbidding the sale and manufacture of any liquor which was, in fact, non-intoxicating, whether it contained more or less than one-half of 1% of alcohol. The Court, however, without stating or discussing this contention, cited the war prohibition cases in support of the conclusion that while "recognizing that there are limits beyond which Congress cannot go in treating beverages as within its power of enforcement, we think those limits are not transcended by the provision of the Volstead Act."

The Volstead Act provided for drastic enforcement, and arms the Government, through the Commissioner of Internal Revenue, with ample powers to punish and suppress any evasion. The regulations under this Act governing physicians' prescriptions and the procuring of wine for sacramental purposes are also drastic.

The Act supplementary to the National Prohibition Act approved Nov. 23 1921 contains still more strict enforcement provisions. It forbids physicians to prescribe for medicinal purposes other than spirituous and vinous liquor, and no physician may prescribe or any person sell or furnish on prescription any vinous liquor that contains more than 24% of alcohol by volume and not more than a quarter gallon or any quantity of such liquor containing more than one pint of alcohol for the use of any person within a period of ten days. This may seem to be an unnecessary and unwarranted interference with medical science, but it indicates that no power was likely to be refused that the administration authorities might find necessary to make enforcement effective. Other provisions giving the enforcing authorities control over importations for non-beverage purposes make it clear that both this Act and the National Prohibition Act apply to all territory subject to the jurisdiction of the United States and specifically continue in force all laws in regard to the manufacture and taxation of and traffic in intoxicating liquor and their several penalties as in force when the National Prohibition Act was enacted. Although the effectiveness and justice of these provisions cannot be accurately judged at present, they at least assisted materially towards enforcing national prohibition.

The question of the meaning of "concurrent power" to enforce the Eighteenth Amendment was also settled by the Supreme

Court in *Hawke v. Smith*, in which the Supreme Court held that the provision of the Amendment in this connection was within the amending power, was a part of the Constitution and "must be respected and given effect the same as other provisions of that instrument," was "operative throughout the entire territorial limits of the United States" and "of its own force invalidates every legislative act, whether by Congress, by a State Legislature, or by a Territorial Assembly, which authorizes or sanctions what the section forbids." The second section of the Amendment declared that "the Congress and the several states shall have concurrent power to enforce this article by appropriate legislation." The Supreme Court said that this "does not enable Congress or the several states to defeat or thwart the prohibition, but only to enforce it by appropriate legislation. The words 'concurrent power,' in that section, do not mean joint power, or require that legislation thereunder by Congress to be effective shall be approved or sanctioned by the several states or any of them; nor do they mean that the power to enforce is divided between Congress and the several states along the lines which separate or distinguish foreign and interstate commerce from intrastate affairs. The power conferred to Congress by that section, while not exclusive, is territorially coextensive with the prohibition of the first section, embraces manufacture and other intrastate transactions as well as importation, exportation and interstate traffic, and is in no wise dependent on or affected by any action or inaction on the part of the several states or any of them." The prohibitionists could scarcely have hoped for a more sweeping endorsement, and the decision may be fairly considered further evidence of the widespread popular desire for effective national prohibition.

State Action.—Statewide prohibition had existed in 1910 in only nine states—one of them in New England (Maine); three in the middle-west (North Dakota, Kansas and Oklahoma); and five in the south (North Carolina, Georgia, Alabama, Mississippi and Tennessee). Not till 1914 did any greater tendency to statewide prohibition show itself, with the exception of an amendment of the state Constitution of West Virginia in 1912. But during the five years 1914-9 half the states adopted statewide prohibition, and these represented every section of the country, although they did not include some of the most populous states with large urban centres. In 1914 statewide prohibition was adopted by Colorado, Oregon, Virginia, Washington; in 1915 by Alabama, Arizona, South Carolina; in 1916 by Arkansas, Idaho, Iowa, Michigan, Montana, Nebraska, South Dakota; in 1917 by the District of Columbia, Indiana, New Hampshire, New Mexico; in 1918 by Florida, Nevada, Ohio, Utah; in 1919 by Kentucky and Texas.

From 1910 to 1914, and in lesser degree until 1920, there was meanwhile a continued struggle as to local option in states where statewide prohibition was not adopted with considerable fluctuation in the proportion of dry and wet areas or counties or towns, as the case might be, within the several states, and sometimes with the further fluctuation that the same area became dry at one election and wet at the next. Local option seems to have had its first trial in the United States in Indiana as early as 1832; when in 1881 Massachusetts adopted local option after extensive experiment with prohibition and ordinary forms of licence, that state became a model for other states in its local option law; local option in 1910 prevailed in 33 states. In Pennsylvania, where the licences were granted by the courts of quarter sessions and the judges elected by the people, local option virtually obtained, because elections of judges often turned on the question of whether or not licences should be granted in a given community; and in New Jersey some communities, by reason of the provisions of special municipal charters, enjoyed the privilege of local option. It was estimated in 1910 that the extent of the dry areas of the United States was to that of the wet areas approximately as seven is to five. The total pop., however, living in dry areas was approximately 41,500,000 to 46,000,000 in the wet areas.

Outside prohibition areas and local option areas there remained little territory in 1920 under other forms of licence or regulation;

the most notable exception being the dispensary system in South Carolina, which was still in operation, however, in only six counties out of 22 that previously had state dispensaries; besides these there were 32 counties dry under local option.

Experiments with local option provided valuable tests of the spread of prohibition sentiment. A writer in the *National Municipal Review* for Oct. 1916, dealing with local option in the United States, stated that at that time 80% of the land area of the United States was under prohibition, affecting 54% of the pop. of the country; in other words that more than one-half of the pop. of the United States, spread over four-fifths of its area, was without licensed supply of intoxicants. In the 26 local option states the percentage of area made dry in that year by local legislation ranged from 18% in Rhode Island to 98.3% in Wyoming, with a median percentage of 78.5. Only three of those states had less than half their area under no licence; seven between one-third and three-fourths, and 16 more than three-fourths. Therefore, said this writer, "with 19 states wholly dry, 16 states more than three-fourths dry and 7 states more than half dry, it would appear from the map that national prohibition requiring the consent of 36 states is not far off."

Liquor Consumption.—Too much importance is often attached to actual statistics of the consumption of liquor as an evidence of the success or failure of local option, and of restriction or prohibition of manufacture and sale. They are by no means conclusive, and especially have slight bearing on the important question, involved in most local option and prohibition enactments, concerning the nature, character and number of saloons and places where intoxicating beverages are sold and consumed. The annexed official figures from the *United States Statistical Abstract* for 1920 give statistics for the consumption *per capita* of distilled spirits, wines and malt liquors for beverage purposes, from 1850 to 1920.

United States Annual Consumption per capita of Distilled Spirits, Wines, and Malt Liquors, 1850 to 1920; in gallons.

Year ended June 30	Distilled Spirits	Wines	Malt Liquors	All Liquors and Wines
1850	2.24	.27	1.58	4.08
1860	2.86	.34	3.22	6.43

*Average for the period.

Influences Behind Prohibition.—The facts and figures already set forth should help to indicate what were the influences which brought together the local, state and national forces, and led to the adoption of national prohibition in 1920, as well as to its virtual enforcement as a war measure July 1 1919, throughout the area of the United States and the territory subject to its jurisdiction. The movement was not to be ascribed, as some publicists have seemed inclined to believe, to a state of exaltation induced by the war. Neither was it due to the absence of many male voters engaged in military service and perhaps not able to make their opinions effective in the matter. Prohibition had its roots and causes outside of and far antedating these sentiments and experiences. The continuously rising standard of living of the masses in both urban and rural communities from 1910 to 1918 had much influence. The industrial demands for efficiency, and the growth of scientific knowledge about its requirements, had an important and increasing effect. Americans of all classes in increasing numbers perceived that,

quite irrespective of their personal habits or desires with respect to the consumption of alcohol, they could not secure the advantages of abstinence, or of moderate and perhaps harmless consumption, on the part of the weaker and more numerous members of any community, unless they themselves were willing to forgo the liberty of personal consumption, even though they belonged to the minority whose efficiency might not in any case be seriously impaired. Enlightened opinion was also shown in the increasing regard for public health, and the measures which the nation as a whole, and the public authorities in most of its component divisions, were taking to promote it. The physiological effect of small doses of alcohol on physical strength and on mental processes had been studied by scientists for many years; and the activities of the leading life-insurance companies, during the decade here under review, in the dissemination of information with respect to personal and public hygiene, had also exerted a considerable influence upon the movement. The published statements of the life-insurance companies, analysing their mortality experience, have generally been regarded as unbiassed, but have not been unchallenged or free from conflicting interpretation. Their conclusions, however, steadily served to support the total abstinence arguments as to industrial efficiency and public health, and they were widely circulated by many of the companies in such a way as to exert an effective educational influence. Mr. Arthur Hunter, actuary of the New York Life Insurance Co., in a paper read before the National Conference of Charities and Correction in Indianapolis in 1916, presented a survey of this material in which he claimed that the American statistics, many of which were then only recently available in published form, corroborated the English data in indicating that total abstinence decidedly increased longevity. He said, "the experience of the seven American life insurance companies (and one Canadian company whose records had been studied) has proved that abstainers have from 10% to 30% lower mortality than non-abstainers, and there is no good reason for believing that if the other companies compiled their statistics there would be any different result, providing the companies exercised the same care in accepting abstainers and non-abstainers."

Lastly, and of as much weight, it would seem, as all the other reasons combined, there was among all classes a growing hostility to the liquor saloon, as a mischievous agency, largely controlled and dominated by anti-social influences, and by persons and corporations actuated by a strong motive of private profit. Furthermore, the liquor saloon was gaining a power in politics, and a control of matters affecting the social life and general welfare of the people, which made its growth disproportionate to that of any other social institution in the country. The public perceived the increasing political influence of the saloon, and the failure everywhere of the various experiments to develop a substitute for it, or, indeed, to organize any other successful centre of recreation, social intercourse and community life, in competition with saloons supported and controlled by the profits of the liquor industry. A formidable body of public opinion united many persons who were neither total abstainers nor wholly convinced by the economic efficiency and health arguments against alcohol. Nevertheless they were sure that drastic measures were necessary, even if they involved heavy personal sacrifice on the part of many persons, to rid the communities in which they resided, as well as those in which they did business, of the baneful results and by-products of the saloon. Thus many who never would have voted for state prohibition, and who were even disappointed with the general outcome of local option, were prepared, when the issue was presented, to support and defend national prohibition.

Results.—Various efforts were made between Jan. 1920 and the autumn of 1921 to appraise the economic results and the effectiveness of the enforcement of national prohibition. But there had not yet been time to get accurate and convincing statistics or to know how to make allowance for purely accidental factors. Adjustment to the new conditions was still going on, and the existence of old stocks of liquor and wine introduced

an inevitable complication. In the case of war prohibition there was a tolerated delay of 7½ months, which the Supreme Court, in its decision upholding the war prohibition enactment, practically stated was a reasonable period, in lieu of compensation, to enable liquor dealers to dispose of liquors on hand. It was still necessary in the autumn of 1921 to depend largely upon the judgment of trained observers, who could be trusted to interpret partial but significant statistics. Of local and partial data there was no lack. *The Survey* for Jan. 27 1920, speaking of six months of the enforcement of war prohibition, said: "Thus the fact of national prohibition comes to pass without any of the dire disasters predicted—great bodies of men are not jobless; the breweries are not idle, but have turned to the making of soft drinks and ice cream; labor has not refused to work without beer. . . ; real-estate values have not slumped; in fact, the rentals charged to cigar stores, soda fountains, lunch counters, groceries and such like which are moving into the vacant saloons with all possible speed, are higher than they were; there has not been a reign of terror by outraged men demanding the return of their personal liberty." Another study made by *The Survey* and published Nov. 6 1920, of the city of Grand Rapids, Mich. (located in a state under constitutional prohibition since 1916), says that Grand Rapids in 1920 was practically free from drunkenness if not from drink; prohibition had all but emptied the county gaol; the county farm had run down for lack of prison labour; the police force had been greatly reduced; the withdrawal of liquor from dance and social halls had closed prolific sources of immorality and crime; and the number of arrests in two years had been cut in half.

A study under the direction of the Federal Council of Churches was made by the head of a social settlement in Buffalo, who visited eight cities, including three of the largest—New York, Philadelphia and Chicago—and the smaller cities of Washington, Harrisburg, Columbus, Detroit and Buffalo, examining the police returns, hospital returns, reports of lodging houses, charitable and community organizations, during the month of April 1920. Most of his material is from official sources and shows a decrease in the number of arrests in cities far apart, which cannot be explained by the operation of the usual causes of fluctuation. Apparently prohibition was the only factor common to all of these returns and operating upon them alike. Other reports, from many sources, of similar character show that throughout 1920 arrests for drunkenness and for all crimes in the principal cities diminished. In Philadelphia the total for the dry six months of 1919 compared with the wet six months of that year showed a decrease of 40% (47,000 to 28,530), and the chief resident physician of the Philadelphia General Hospital stated that there had been no increase in the use of drugs since prohibition.

Fifty-nine cities of the United States having a pop. of 30,000 or over and a combined pop. of over 20,000,000 (including New York, Chicago and Philadelphia) give the following official figures for arrests for drunkenness in the four successive years 1917-20: 316,842, 260,169, 172,659 and 109,768. Indiana shows 70% fewer arrests in 1920 for drunkenness than in 1917, the last year when the state was wet, for 39 cities with a combined pop. of nearly one million. Boston reports 5,000 fewer arrests in 1920 for all causes than for drunkenness alone in 1919; the state of Massachusetts reports 32,580 arrests for drunkenness in 1920 compared with 77,925 in 1919; Connecticut had 943 arrests for drunkenness in 1920 against 3,777 in 1919; New York City a decrease from 14,182 in 1917 to 5,813 in 1920; St. Louis a decrease from 2,605 in 1919 to 691 in 1920. A similar tendency in many cities is apparent in the returns for 1920.

Since prohibition, high wages and continuous employment came together during the year July 1 1919 to June 30 1920, it is difficult to state with certainty which of the three was the cause, or the major cause, of the increase in savings bank accounts, or of the decrease in industrial accidents reported during that period. An official statement of the Comptroller of the Currency given out in Washington Jan. 22 1920 stated that in national banks alone 880,949 new accounts were opened in the first 4½

months of the fiscal year beginning July 1 1919, and that the increase in the number of depositors in state and private banks, though not available, was known to be far greater than the increase of depositors in national banks. The Comptroller's official report (*48th Annual Report*) for the year ended Oct. 31 1920 states: "In the number of depositors or deposit accounts in national banks all previous records were exceeded, official reports showing that on June 30 1920 there were 50,580,177 deposit accounts in all national banks. This was an increase of 2,279,877 (12½%) over June 30 1919. There is now approximately one depositor in the national banks for every five of our population."

The most disinterested and intelligent observers, accustomed to judging public conditions and social facts, differed widely in their verdicts on prohibition, its economic results and general benefits or disadvantages to the public welfare in the first year of national prohibition. That is likely to be true for several years to come. The more authoritative opinion, however, seemed to be that the first effects had been generally beneficial; that the popular sentiment in support of effective prohibition was gaining in strength, and that the experiment would be continued and developed. The fears of lurking danger to social institutions or to the moral integrity of the people (which some critics believed to be inherent in prohibition), seemed likely to be outweighed by the economic and political advantages of freedom from the saloon, and the semblance, at least, of more orderly communities, less petty crime and less abject poverty. The majority of moderate drinkers seemed to be willing to sacrifice their personal liberty for these desirable results. The intemperate constitute a minority as compared with the total abstainers plus a majority of those who had been moderate users of intoxicating beverages, and their number may be expected to diminish from year to year. The business interests which were thought to be menaced by prohibition found, at the time when national and wartime prohibition went into effect, means of readjustment without great loss and without inflicting on the nation the burden of any scheme of compensation. The outlook for the future was in 1921 one of hope that new forces and new funds had now been released, which might be directed to providing normal recreation and facilities for social and community life which the saloon did not provide, but for which its very existence had precluded other provision being made.

U.S. War-emergency Measures.—After the entry of the United States into the World War, Federal legislation began with the Draft law of May 18 1917, Section 12 of which authorized the President to make regulations for the prohibition of the sale of alcoholic liquors in or near military camps and to officers and enlisted men of the army. An Act to promote the efficiency of the U.S. navy, approved Oct. 6 1917, extended these provisions to include the navy and all places for training and mobilization connected with the naval service. This section made it unlawful to sell or supply intoxicating liquors to any military or naval station, cantonment, camp, fort, or officers' or enlisted men's club, or to sell intoxicating liquor, including beer, ale or wine, to any officer or member of the military force while in uniform. The Food Control Act of Aug. 10 1917 prohibited the use of foods, fruits or food materials in the production of distilled spirits for beverage purposes, but authorized the President to prescribe rules for their use in the production of distilled spirits for other purposes. It provided also that distilled spirits should not be imported into the United States, and that whenever the President should find that limitation, regulation or prohibition of the use of foods, fruits or food materials in making malt or vinous liquors for beverage purposes, or that the reduction of the alcoholic content of such liquors is essential for food conservation, he should be authorized to prescribe and give public notice of such limitation, prohibition or reduction as might be necessary. This Act also authorized the President to commandeer and pay for distilled spirits needed for the manufacture of munitions or military supplies.

The so-called War Prohibition Act, enacted Nov. 21 1918, 16 days after the signing of the Armistice, was an amendment to the Agricultural Appropriation Bill, and provided that from June 30 1919 until the conclusion of the war and of demobilization, the date to be determined and proclaimed by the President, it should be unlawful to sell for beverage purpose any distilled spirits or to withdraw distilled spirits from bond except for export. It also provided that after May 1 1919 no grains, cereals, fruit or other food products should be used in the manufacture or production of beer, wine or other intoxicating malt or vinous liquor for beverage purposes, and after June 30 1919 no beer, wine or other intoxicating malt or vinous

liquor should be sold for beverage purposes except for export, until the conclusion of the war and of demobilization, the date to be determined by the President. This Act also prohibited the importation, from the date of its approval until the period of its termination, of distilled malt, vinous or other intoxicating liquors. The President was further authorized by the Act to establish zones about coal mines, munition factories, shipbuilding plants or wherever necessary to facilitate war work, in which strict prohibition should be made effective under heavy penalties. This Act continued in force until national prohibition came into force by reason of the refusal of the President to declare demobilization to have been completed before that date, and the section of the Act authorizing the President to establish special zones as above described was incorporated from a joint resolution of Congress, having the force of law from the earlier date of Sept. 12 1918.

The Prohibition Enforcement Law or Volstead Act, enacted Oct. 28 1919, three months before national prohibition came into effect, provided for the enforcement of both the War Prohibition Act and the Eighteenth Amendment. The President exercised the powers conferred on him under the Food Control Act of Aug. 10 1917, and under it the manufacture of distilled spirits in the United States was prohibited on and after Sept. 8 1917. Through the Food Administration the President also stopped the use of food materials in the manufacture of beer on Dec. 1 1918. All these measures were strictly enforced and achieved their major purposes by securing conservation and the maintenance of discipline and sobriety in all places where men in uniform were stationed. They did not affect the civilian population because of the short period of prohibition of manufacture, and because of the existing stocks in territory where local or state legislation permitted its sale. No state legislation was necessary to carry out the purposes of the special war period restrictions. (S. McC. L.)

PROPAGANDA, the term applied to a concerted scheme for the promotion of a doctrine or practice; more generally, the effort to influence opinion; by a false analogy from such plural words as "memoranda," frequently applied to the means by which a propaganda is conducted. The objective of a propaganda is to promote the interests of those who contrive it, rather than to benefit those to whom it is addressed; in advertisement to sell an article; in publicity to state a case; in politics to forward a policy; in war to bring victory. This differentiates it from the diffusion of useful knowledge; the evangel of a mission; publication of the cure for a disease. In such objectives there may be a secondary advantage to the contriver, but to benefit the subjects of the effort is the leading motive. Similarly those engaged in a propaganda may genuinely believe that success will be an advantage to those whom they address, but the stimulus to their action is their own cause. The differentia of a propaganda is that it is self-seeking, whether the object be worthy or unworthy, intrinsically, or in the minds of its promoters.

Statements or arguments known to be self-interested tend to raise suspicion. A wide examination of propagandas supplies an empirical argument in justification of such an attitude. Indeed, casuistically considered, indifference to truth is a characteristic of propaganda. Truth is valuable only so far as it is effective. The whole truth would generally be superfluous and almost always misleading; the selections made range from a high percentage to a minus quantity. The time factor is vital. If a quick sale or a decisive victory is possible, opportunism may be more useful than exactitude. If a permanent market is to be opened or a protracted campaign is expected, caution is required in suppression or in misstatement. Although truth may thus be irrelevant to the success of a propaganda, it does not follow that those engaged in it are consciously unethical. Doubtless, in every effort to control opinion, there are persons either indifferent to justification, or who justify the means by the end. But the more the emotions are excited, whether by patriotism or by cupidity, by pride or by pity, the more the critical faculties are inhibited. It is a quality of propaganda, as of counter-propaganda, that high-minded persons on both sides commend their cause by identical arguments, and that high-strung persons soon come to believe what they wish to be true. Their character and their enthusiasm lend weight to many partial statements, or even make false coin ring true.

The suspicions aroused by an admitted propaganda lessen its effectiveness, from which it follows that much of the work has to be furtive. Part of the task, and that the more easy, is to whip up existing inclinations, but the more arduous and the more

frequent duty is to reverse or to create opinion. Efforts are therefore made to present "tendencious" matter as impartial. The simplest case is seen in the familiar methods of newspaper advertisement. The crudest form is a direct printed recommendation of an object, obviously paid for. More subtle, but still plainly a paid advertisement, is a general paragraph in the "News" columns, with the letters *Adv.* at the foot. Best of all is commendation in the editorial columns or description disguised as news, these methods being seldom adopted in the responsible Press of the better kind, but familiar in organs subsidized to support an interest, possibly with a free hand on everything except that interest.

The methods of a propaganda are limited only by the resources and the ingenuity of its promoters. They may be studied in their most intensive form in the propagandist efforts during a war; the magnitude of the object secures the necessary funds, and at the same time attracts the services of persons of more intellect and character than would usually devote themselves to such a pursuit; in the atmosphere of war, moreover, truth, like many other fine qualities of humanity, is judged by expediency, with varying answers.

The use of propaganda in war dates from remote antiquity. It is plain that Herodotus, with his alert and modern mind, suspected the possibility of "working" the oracles whose pronouncements had so great an influence. But in *Urania VIII.*, 22, he describes a propagandist effort made in the Persian War by Themistocles, son of Neocles, which in intention and method might have occurred in the recent World War:—

"Themistocles, having selected the best sailing ships of the Athenians, went to the places where there was water fit for drinking, and engraved upon the stones inscriptions, which the Ionians, upon arriving next day at Artemisium, read. The inscriptions were to this effect: 'Men of Ionia, you do wrong in fighting against your fathers, and helping to enslave Greece: rather, therefore, come over to us; or, if you cannot do that, withdraw your forces from the contest, and entreat the Carians to do the same. But if neither of these things is possible, and you are bound by too strong a necessity to revolt, yet in action, when we are engaged, behave ill on purpose, remembering that you are descended from us, and that the enmity of the barbarian against us originally sprung from you.' Themistocles, in my opinion, wrote this with two objects in view; that either, if the inscriptions escaped the notice of the king, he might induce the Ionians to change sides and come over to them; or, if they were reported to him, and made a subject of accusation before Xerxes, they might make the Ionians suspected, and cause them to be excluded from the sea-fights." (Herodotus VIII., *Urania* 22.)

Propaganda on similar lines has been conducted in almost every war in history, but until the World War (1914-18) chiefly as a subsidiary part of the actual military or naval operations. Clausewitz, the Polish-Prussian officer (1780-1831) whose works on the conduct of war were translated into most modern languages and formed the basis of most military theory, laid it down partly as a prediction and partly as a precept that war must be waged with the whole force of a nation. Military propaganda may therefore be defined as the attempt to add the psychological factor to the other resources of warfare. It may be considered formally under four heads:—(1) Control of Home Opinion; (2) Control of Neutral Opinion; (3) Control of Allied Opinion; (4) Control of Enemy Opinion. Counter-propaganda is the effort to counter the operations of the Enemy.

(1) *Control of Home Opinion.*—In modern times even the most autocratic ruler or state cannot hope to conduct a protracted war, or a war that brings a great burden on a nation, or a war that sways with doubtful success, unless public opinion is favourable. A large part of propaganda must therefore be for home consumption. It will proclaim the certainty of victory, describe actual and prospective military and naval triumphs, obliterate or explain reverses. It will vaunt economic strength, financial resources, power of organization; it will explain difficulties in the supply of food and raw materials, give the reasons for vexatious regulations and interferences with the ordinary routine of trade. When the war appears to be going unfavourably, it will urge the need of endurance. But it will not neglect the moral appeal. It will insist that the war is one of defence, or at least for an unselfish purpose; that victory will be for the good

of the world, will be a permanent triumph of right over wrong. At the same time, according to the mentality of the nation, it will insist on historical military glory, on the pursuit of the national aspirations such as recovery of ancient rights, redress of old wrongs, material benefits to be derived from victory, appalling consequences of defeat. The outrageous conduct of the enemy, his unnecessary cruelty, his breach of international law are all important.

(2). *Control of Neutral Opinion.*—The propaganda addressed to Neutrals covers much of the same ground, with the least possible stress on the interested motives, much stress on the defensive and inevitable sides of the war, the certainty of victory and its benefit to all humanity. Very careful attention is devoted to explaining as necessities all the steps that have interfered with the rights of Neutrals or have been positively harmful to them. Much care is given to exposition of the thesis that victory would also be to the benefit of the Neutrals.

(3). *Control of Allied Opinion.*—This is of great difficulty and of increasing importance with the prolongation of a war. It is necessary to anticipate points of friction, gloss over points of diverging interest, pay very careful deference to the Allied contribution to the common cause and to the absolute identity of interest. In the World War many mistakes were made in this aspect of propaganda, but by none more conspicuously than by the Germans, whose treatment of their Allies was marked by compulsion rather than by persuasion.

(4). *Control of Enemy Opinion.*—The efforts in this direction fall under three main heads:—Insistence that victory is certain and that prolongation of the war is only increasing the inevitable disaster to the Enemy. Attempts to stir up disaffection amongst the Enemy's Allies; attempts to stir up internal trouble in the Enemy's country.

The four sub-divisions enumerated above cover the main purposes of both propaganda and counter-propaganda, but they are only formal, and it is of vital importance to remember that under modern conditions a propaganda cannot be limited to the group for which it was intended. The most rigid censorship and scrutiny at the frontiers did not retain within Allied Countries or in Germany what was prepared for home consumption, with the result that the propaganda of one camp was often used almost without alteration as counter-propaganda in another. Neutral countries were the battle-ground in which contending propagandas met, and where statements of alleged facts and arguments came in contact.

THE BRITISH EFFORT IN THE WORLD WAR.—In the usual British fashion propaganda in the World War came into existence by the extension of the normal duties of several different bodies, with the result that there was much overlapping, as well as many gaps and considerable diversity of aim and method. From time to time new bodies were created, partly absorbing, partly replacing and partly combining the agencies in operation. Even when the Armistice came, no complete organization had been achieved, and the very great success actually obtained may be ascribed to the flexibility of the methods, the devotion of those who conducted them, and a very remarkable unity of purpose which overbore such personal rivalries as are inevitable in human affairs. A logical and consecutive account of the British propaganda is impossible. No complete organization ever existed, and as much of the most successful work was necessarily conducted secretly, and much was done by private enterprise, for instance by the spontaneous patriotism of universities, publishers, newspapers and private persons, an exhaustive description is impossible. The official side of it was conducted at first chiefly by the Foreign Office, the War Office and the Admiralty, as extensions or side issues of their normal duties. Many special missions were inaugurated by these bodies, or directly by the Cabinet.

In the beginning of 1918 a special body, the Ministry of Information, under a Cabinet Minister, Lord Beaverbrook, was created to combine and extend British propaganda with special reference to the control of Home and Neutral opinion, and another special body, the Department of Enemy Propaganda (afterwards the British War Mission), under Lord Northcliffe, for the same purpose, with special reference to control of opinion in enemy countries. Under the energetic direction of these two

great publicists and the brilliant staffs they assembled, British propaganda enlarged its sphere, increased its potential and began to approach coherence. The steps of most vital consequence, however, must be attributed to Lord Northcliffe and his staff. They were early impressed with the conception that propaganda must be closely linked with policy. With the willing co-operation of the Ministry of Information, they first secured a general unity of method and purpose in purely British work, and, next, by propaganda conferences in London, extended a similar unity to British, French, Italian and American propaganda. Still later, as the war appeared to be nearing its end, they formed a general committee containing representatives of all the great Departments of State and worked out a Peace Propaganda Policy, to which the assent of the British Cabinet was obtained and which was at once made the basis of all British propaganda. Arrangements had been made for another conference of Allies in which the British Peace Propaganda Policy was to be co-ordinated with the policy of our Allies, when the signing of the Armistice made further effort of this kind unnecessary. Later in this article the steps which led to this ultimate co-ordination will be described more fully, or will become more apparent as the scattered agencies which led to it have been explained. But it is pertinent here to observe that the final stage, reached by slow experience, should have been the initial stage. In any national propaganda, the national policy, if such indeed exist, should be within the cognizance of those who have to create and direct the machinery for endeavouring to control opinion.

From the outbreak of the war in 1914 to the end of 1915, the official organization of British propaganda was highly tentative. The task of creating and directing public opinion during war had never before been a function of British Governments and did not consort well with the national traditions. In the first months of the war, during Mr. Asquith's Ministry, a War Propaganda Bureau was set up in the National Assurance Offices at Wellington House; a Neutral Press Committee, with special reference to Cabling was established under the Home Office, and a News Department, to deal with the Press, was formed by the Foreign Office. Gradually these three departments came more under the authority of the Secretary of State for Foreign Affairs; but they operated to a large extent as independent agencies without central control.

The Admiralty and the War Office had to exercise strict control over the publication of news relating to actual or proposed operations and other matters relating to the navy and army. The censorship which they had to exercise strictly for military reasons, gradually acquired a wider purpose and passed into a dissemination of news essentially propagandist. The direct effect of this bias given to news was upon home opinion, but naturally passed from home countries to neutrals, and from neutrals to enemies. It had therefore the legitimate objects not only of concealing what it was useful to conceal, but of making suggestions which might deceive. From indirect or accidental propaganda, it passed over to deliberate propaganda. Similarly the official representatives of the Foreign Office in Allied and neutral countries quickly found that their routine duties of explaining the intentions of the British Government, and of assisting public and private British interests, necessarily acquired a propagandist bias. As there were obvious inconveniences in this course, the propagandist activities in foreign countries gradually became detached from the official diplomatic activities, and acquired direct relationship with special departments at home. A similar series of events took place in the case of the representatives of the British army and navy in foreign countries, especially those attached to the Secret Services. As their efforts became more propagandist, it was convenient to separate them. Thus in various ways a propagandist service crystallized out of normal services.

During this period, and, indeed until the end of the war, the voluntary work of the great newspapers and publishing houses made an important contribution to British propaganda. It is perhaps necessary to insist on the voluntary side of this work. It has never been the tradition of the British Government to

subsidize or to control the British Press, and although some efforts were made in that direction, they were signal failures. The great newspapers and the great publishing houses jealously maintained their independence and their right of criticism; they were willing to accept censorship so far as it was supposed to prevent the leaking of information that might be of service to the enemy. But they fought bitterly, and successfully, any attempts of the Censorship to overstep the bounds of military needs. (See CENSORSHIP.) The independence of their attitude and the strength of their patriotism combined to make their voluntary propagandist effort of the utmost importance.

Ministry of Information.—It will be convenient to deal first with the grouping of propagandist agencies under the Department, later the Ministry, of Information, as this body was the first to combine a number of scattered bodies under one direction, although, as will be shown later, the War Office, under the Directorate of Military Information, created earlier an extensive propagandist headquarters.

The Department of Information was formed by a resolution of the War Cabinet on Feb. 20 1917. According to that resolution its object was to take over and unify the various foreign propaganda activities, and to act as a general publicity bureau under the War Cabinet. Col. John Buchan was brought back from France and appointed Director of Information. Propaganda thus acquired its own specific organization separate from other Government Offices and directly under the Prime Minister. There was necessarily much overlapping with the War Office, but on the whole the Department of Information worked toward the control of civilian opinion, the War Office to that of military opinion; the former concentrated attention on political and general subjects, the latter on military subjects.

The Department of Information, during the time of its existence, covered the work of British propaganda in Allied, neutral and enemy countries. It was arranged in four sections:—

- (a) An administrative section, divided into branches, corresponding to the different countries, each branch being under the charge of an official who was a specialist in that geographical area.
- (b) A producing section which dealt with literature and art and was virtually a large publishing establishment.
- (c) A producing section concerned with cables and wireless and the distribution of cinema films and press articles.
- (d) A political intelligence section, which provided reports upon political and civil matters in foreign countries.

Foreign propaganda was conducted (a) among foreigners on a visit to Britain or resident there as correspondents, and (b) in the foreign countries themselves. (a) The first task involved hospitality to foreign visitors, the securing of facilities for Allied and neutral correspondents, and the arranging of visits to the British front, the British fleet and other centres of interest for writers and public men from Allied and neutral countries. Three châteaux on the western front were used for guests by the Department of Information—one for American visitors, one for the Allied and neutral press, and one for visitors in general. A large number of distinguished foreigners were invited to Britain, since it was held, with reason, that the best propaganda in any country was that done by the citizens of the country themselves. (b) Propaganda in foreign countries was conducted by the issue of a very large number of publications in different languages, including pictorial journals, pamphlets and books. The *War Pictorial* was issued monthly in eight editions with a circulation of over 700,000. Six oriental papers were published fortnightly in different languages, and the Department published fortnightly journals in Spanish, Greek, and Portuguese. Exhibitions of photographs and war films were arranged throughout the world. Over a million words of propaganda material a month were cabled by Reuter, and there were also daily cable and wireless messages sent from the Department. An average of 400 articles per week was sent out to the foreign press. Bureaux of Information were established in the different Allied and neutral countries, which assisted in distributing the material prepared by the Department, and also acted as intelligence centres. A special section dealt with propaganda in enemy countries by means of articles and cables

printed in the newspapers of adjacent neutral States, and by aeroplane and balloon distribution on the different fronts.

The organization of the Department of Information obviously left much to be desired. In the first place it was not a ministry and had no ministerial head. This led to two disadvantages: the War Cabinet had little time to spare for the supervision and direction of its policy, and in dealing with other ministries it lacked the prestige necessary to safeguard its interests and enforce its requirements. Again, it had no single domicile, being housed in four different parts of London, and this led not only to a great deal of delay in its work, but prevented it being organized according to the normal plan of a Government office.

The Ministry of Information was constituted on March 4 1918, with Lord Beaverbrook as minister. It took over the whole organization of the old Department of Information, with the exception of the Political Intelligence branch, which was transferred to the Foreign Office, and the section dealing with enemy propaganda (excluding Turkey and the Middle East), which was transferred to Lord Northcliffe. The new Ministry was organized on the normal lines of a Government department, and was able to draw for its increased staff upon a large number of distinguished volunteer workers. The new Ministry had four main departments:—

(1). The Intelligence Department received and digested all information necessary to the efficient work of propaganda in the different countries, translating policy into terms of propaganda. The special cable and wireless messages which were issued daily were prepared under the direct supervision of this Department.

(2). The Propaganda Department was in charge of the actual administration of propaganda in foreign countries. Under its director there was a section for each important country, or group of countries. Each section was in charge of a "National" at the headquarters of the Ministry, and in each foreign area there was a corresponding organization which carried on the work in that area. Over each of the main sections there was a special officer called the controller, whose business it was to supervise the work of the "Nationals," more especially with a view to the expenditure of public money.

(3). The material for propaganda—apart from the cables and wireless, which were directly under the Intelligence Department—consisted of press articles prepared or arranged for at the Ministry's headquarters; literature in the shape of journals and pamphlets; and war photographs, films, pictures. The preparation of pictures, photographs and films, as well as their distribution, was directly controlled by the minister, and was no longer in the hands of War Office Committees, as had been the case with the old Department of Information.

(4). The Ministry gave special attention to what might be called "personal" propaganda, securing facilities for foreign correspondents to visit British centres of interest and to meet representative British public men, and, generally speaking, the widening of sympathy for Britain's cause by the personal and social contact of Britons with the citizens of other lands. In this direction the work was large and ramified. A Facilities branch arranged for visits and entertainments; an Overseas Press Centre acted as a clearing house between all branches of the Ministry and the correspondents of the Overseas Press in this country; a special organization dealt with the entertainment of American troops in Britain. Besides the work of personal propaganda done in Britain itself, much was done by representatives of the Ministry abroad, who acted as popular and democratic ambassadors, keeping in touch, not with official, but with unofficial powers.

The nature of its duties made it impossible for the Ministry of Information to be a rigid organization like an ordinary Government office. Propaganda is not a static thing and can never be standardized, and the constitution of a propaganda department had to be adapted to so fluctuating a subject matter. Constant revision was necessary, both in material and method. Moreover, the larger part of the work of the Ministry had to be done quietly and unofficially, and without advertisement, since popular opinion in every country is so delicate an instrument that attempts to play upon it in the name of a foreign government, even an Allied Government, would without doubt have been resented. The anomalous character of its duties was reflected in the curious variety of its staff. It is probable that never before in any Government department had there been so many distinguished men of a type so remote from that of the normal official. All varieties of talent were needed—the skilled journalist and the expert in publicity for the actual business of

propaganda, the experienced business man for the control and expenditure of machinery, and the student of public affairs for Intelligence and Policy.

Directorate of Military Intelligence.—Until the end of 1915, the Intelligence Section of G.H.Q. (France), and the Director of Special Intelligence at the War Office, made somewhat casual efforts in the direction of propaganda at home, abroad and amongst the enemy forces, and did more in the direction of acquiring information about the propagandist activities of the enemy. The supreme military authorities, however, either attached little value to propaganda, or were more absorbed by their directly combatant functions, and gave no encouragement to the development of propaganda. In the beginning of 1916 Gen. Sir George Macdonough returned from France to become Director of Intelligence on the Imperial General Staff. Thenceforward until the end of the war, a branch of his directorate was devoted to propaganda with continually increasing intensity. Under his stimulation and with the encouragement and the active assistance of Brig.-Gen. Cockerill, his second-in-command, a small group of men, half of them regular officers and half distinguished civilians with temporary commissions, a very large and successful organization was built up. It worked in close cooperation with General Headquarters at the various fronts and with the propagandist agencies in England. Its command of material drawn from all the branches, open and secret, of the Directorate of Military Intelligence, and its close connexion with the fighting services, gave it very large opportunities, of which it took full advantage; on the other hand, the fact that it was a branch of the War Office, run on strict military lines, prevented the full extent of its activities being known, and the credit of much that it accomplished was assigned to organizations more accustomed to work before the footlights.

Reports, captured documents, photographs and any other matter with a possible propagandist use, were collected from all the fronts. Samples of all propaganda prepared by the enemy were obtained from neutral countries, through the postal censorship, by direct capture, from the navy and from all other available sources. Details of the actual fighting operations, stories from the fronts, and all matter tending to show the conditions of fighting on both sides were assembled. Letters written by prisoners of war were read in the special censorship and copies of any judged to be of utility were preserved for reproduction in *facsimile*. Illustrated booklets describing the happy conditions of enemy prisoners in British camps were prepared. The foreign press, especially that from enemy countries, was regularly read, and extracts taken. From these and similar materials propaganda was prepared for distribution, partly by the regular staff of the section, partly by distinguished civilians who gave their services, and largely by wounded or otherwise disabled officers of literary capacity seconded for the purpose. The propagandist material prepared in this way was first carefully censored from the military point of view, in case inadvertently it might contain information which it was desired to keep secret. It was next submitted, especially where it contained matter with any political significance, to the Foreign Office. It was then ready for use. A staff of linguists was maintained to examine and translate material from foreign sources which covered almost every known language. The prepared propaganda, if useful for other than English readers, was translated into foreign languages ranging from Urdu to Spanish, from Russian to Arabic.

A few examples may serve to illustrate the range covered by the War Office propaganda. A German Army Order captured in E. Africa showed contempt or ignorance of Mahomedan religious customs. It was reproduced in *facsimile*, with a translation into every known tongue spoken by Mahomedans. A pamphlet written by Dr. Liebknecht, the German socialist leader, suppressed in Germany, was reproduced in German. Photographs of German prisoners showing their miserable condition on capture, their reception in the British lines with food, chocolate and cigarettes, and their happiness in their ultimate quarters in British prisoner of war camps, were reproduced

as a small album. Letters written home by German prisoners of war, describing the comfortable conditions under which they lived, were reproduced in *facsimile*. An erroneous account of the battle of the Marne, written in Spanish for circulation as German propaganda in S. America, was followed by a correct account with exact maps, written by a British general who had been actually engaged in the battle. Every effort of German propaganda was followed and promptly countered in the same language as that in which it had been written. Perhaps the quickest exchange and counter-exchange took place through a cable and wireless service. All the messages issued by the enemy by cables or wireless telegraphy were intercepted and transmitted at once to the War Office. They were followed by a special staff, and the replies to them often reached their destinations a few hours after the originals, more often than not in time for the same editions of foreign newspapers.

Increasing attention was paid to the unification of the propaganda issued by the Allies, and to the pooling of information useful for propaganda. Regular conferences took place at British and French military headquarters in France for the purpose of co-ordinating propaganda. With the same object constant touch was maintained between the military propagandist staffs in London and Paris. A weekly journal, *Le Courrier de l'Air*, was prepared and issued at the War Office for circulation in the part of Belgium under German occupation. It contained information as to the progress of the war, general news, political intelligence, and much ordinary magazine reading.

Articles suited for British newspapers were offered to editors, and were freely used. These for the most part consisted of descriptions of scenes in the war on various fronts, written by officers who had been engaged in them. Similar matter, and articles covering a wider field, were distributed to English newspapers in every part of the world. A special staff watched the newspapers to observe the kind of articles that were most freely taken by each, so as to suit the supply to the demand. In the same way articles on almost every subject connected with the war were translated into foreign languages and distributed to newspapers in foreign countries. Large quantities of matter were sent to the Department of Information for distribution by their agencies, especially in neutral and Allied countries. There were several military distributing agencies in the Near East, and farther away, of which the largest was an "Arab Bureau" in Egypt. Some of these had local presses at which copy sent from London was set up, but a very large bulk of matter, especially illustrated matter, was prepared and printed in London, and sent out in bulk. According to its objective, it was distributed through vernacular newspapers, or by special agents, who smuggled it into enemy countries.

As regards distribution to enemies, a certain amount of this important side of the propagandist effort was done through the Department of Information, but the War Office itself directed the greater part of the work, especially where it was desired to reach enemy soldiers directly, or the enemy civilian population through them. From the examination of prisoners of war and by the direct admission of the German authorities it became clear that this service was highly effective. Early in 1917 the decision was made to extend considerably the work of preparing and distributing propaganda for the enemy troops on the western front. A special sub-section was created under the charge of an officer who had just completed an analysis of over 2,000 books and pamphlets of enemy origin. At that time there was no objection to the use of aeroplanes for the distribution of literature over the enemy's lines. The sub-section prepared and had translated into German a large quantity of suitable literature, much of it written by the officer in charge of the section (the writer of this article), other matter selected from the work of the Department of Information or from other sections of the War Office. Some of these early efforts were too successful; in particular the Germans objected to a cartoon with the legend "A German Family that has had no losses in the War," depicting the Kaiser and his sons in uniform, on the ground that its distribution was an offence against military discipline.

Captured flying officers accused of distributing propaganda were tried in Germany by court martial and received severe sentences. Although in fact the sentences were not carried out, after negotiations had taken place through a neutral Power between the British and German Governments, the Germans let it be known that any future cases would be treated with the utmost severity. The French continued the use of aeroplanes in spite of this threat. But the British Air Ministry opposed the use of aeroplanes, partly on the ground of the "bad psychological effect of working under such threats, on young pilots and aviators," and partly on the more valid ground that the supply of trained men and of machines was no more than sufficient for the direct purposes of this branch of the forces. After an attempt, obviously impractical, to distinguish between propaganda that could not be regarded as "inflammatory" and that therefore could be distributed by aeroplanes, and propaganda that could not escape this charge, British G.H.Q. accepted the position and decided against the use of aeroplanes for the distribution of literature. The stock of literature prepared for the western front, except such small parts of it as could be used by other army devices, was transferred to the Ministry of Information and to the French army.

The War Office Enemy Propaganda Section then turned to the devising of other possible methods for the distribution of literature by mechanical means. Information was collected from all possible sources, the methods of the enemy being carefully watched. With the assistance of the Aerial Inventions Board and the Munitions Inventions Department, many devices were tried, and as soon as any had reached a promising stage, the officer in charge took it out to France, to discuss its possibilities, and, with the assistance of the intelligence officers of the army, to test it under field conditions.

A section of G.H.Q. Intelligence had obtained great success in dropping homing pigeons and other means of carrying messages on known areas where they could be found by British agents behind the enemy lines. In this work fabric balloons with timing devices for dropping loads at the required localities were employed, but the apparatus on the one hand was unnecessarily exact, and, on the other, much too costly for the distribution of literature. The Germans were found to be using very large balloons of scarlet Japanese paper which carried bundles of newspapers and other matter long distances, sometimes releasing them by slow-burning tinder fuzes. It was clear, however, that this method was haphazard, as balloons and loads destined for the neighbourhood of Verdun not infrequently dropped in Kent. Experiments were undertaken to study the lifting capacity of light balloons, the load and degree of filling that would enable them to rise to an approximately known height, and the arrangement of time fuzes so that they would liberate weights at known distances varying with the strength of the wind. At the same time experiments were made as to the shape, economical mode of manufacture and dimensions of paper balloons, and on the treatment of the paper to lower the rate of diffusion of coal-gas or hydrogen.

A large number of devices such as rockets, grenades and shells were enquired into, but were not adopted because of various objections raised against their use by the military authorities. A device consisting of a fire-balloon, the fabric of which consisted of propaganda sheets joined by strips of touch paper, seemed promising, but did not reach success.

Extensive experiments were carried out with the object of adapting an apparatus invented to distribute light bombs to the distribution of literature. It consisted of a box-kite with an automatic conveyer which carried five-pound loads of propaganda up the cable, liberated them at the required height, and automatically returned for another load, the sheets when liberated being carried to their destination by the wind. The method was extremely good; it was cheap, easy to work, and had a range of upwards of ten miles according to the strength of the wind. But objection to its use at the front was taken by the Air Force on the ground that the cable of the kite would be a danger to aeroplanes.

In connexion with the last-mentioned apparatus, extensive observations were carried out on the wind-driftage of sheets of paper of different shapes and weights, and of the methods of releasing them at height. Experiments were made from aeroplanes and from captive balloons, and the range and conditions of falling were ascertained. It was found, for example, that in a wind of approximately ten miles an hour, a bundle of 150 sheets liberated at a height of 2,500 ft., came to the ground two miles away, scattered over an area 500 yd. square. In higher winds and from greater heights much more distant ranges could be attained. The War Office Propaganda Section accordingly suggested that aeroplanes might be safely used, flying at heights proportioned to the strength of the wind, and the distance of the enemy lines, by flights well within the British lines. But this proposal also was "turned down."

By the end of 1917 it became clear that the use of paper balloons was the only method which would encounter no opposition, and attention was therefore concentrated on producing them on a large scale and on applying the experience gained in other directions to them. By far the largest bulk of propaganda distributed by the Allies on the western front was released from balloons, and it may therefore be of historical interest to describe their final form. The propaganda balloons were made of paper cut in longitudinal panels, with a neck of oiled silk about 18 in. long. Their circumference was approximately 20 ft. and their height when inflated 8 feet. They were liberated inflated nearly to their full capacity—from 90 to 95 cub. ft. of hydrogen. The weight of the balloon was under one pound, the load of propaganda four pounds. The leaflets were attached to a fuze of treated cotton, similar to the tinder of flint pipe-lighters, and burning at the rate of an inch in five minutes. The string of propaganda was tied to the neck of the balloon, and just before liberation a slit was cut in the neck to permit the escape of gas, and the end of the fuze was lighted. The weight and lift were adjusted so that the balloon could rise several thousand feet into the air before the loss of gas due to expansion would have caused a state of equilibrium. At this point the first bundle of leaflets was set free, and the process was continued until, at the end of the run, the last bundle was released. The total time length of the fuze and the attachment of the bundles to it were calculated according to the area which it was desired to reach and the strength of the wind. Experimental improvement of the "dope," by which the rate of diffusion of the gas was lowered, and the manufacture of balloons of double the standard capacity, had made runs of upwards of 150 m. practical, before the Armistice suspended operations. But the bulk of the propaganda was actually scattered over an area of from 10 to 50 m. behind the enemy lines, rest camps and villages occupied by the troops being made the chief targets. Each distribution unit at the front consisted of two motor lorries which carried the balloons, hydrogen cylinders, and personnel to convenient positions, generally from 3 to 4 m. behind the front line.

Early in March 1918, the method of balloon distribution was in full working order, and the War Office Propaganda Section resumed the active preparation of material. The reproduction of selected letters written by prisoners of war was resumed, and *Le Courier de l'Air* was enlarged and improved by the introduction of direct propaganda. A series of leaflets, known as the A.P. (Aerial Propaganda) was begun. The first of these, sent to France in March, was a complete German edition of the British Prime Minister's speech on British War Aims. This had been incompletely reported in the German newspapers, and in the new edition attention was directed to the portions which had been taken out by the German censorship; copy for other leaflets was selected from German and Austrian newspapers, was contributed by G.H.Q. (France), by the War Aims Committee, by the Ministry of Information, and by the new Directorate of Propaganda in Enemy Countries which had been established under Lord Northcliffe. But the whole series was selected, revised, edited, and produced by the War Office, and a very large proportion of the actual leaflets were prepared by the officer-in-charge. The first of the series was sent to France on

March 16, the last, number 95, on Sept. 4; of the whole series over 12 million leaflets were sent to France.

Later, in 1918, when, under the energetic direction of Lord Northcliffe, the machinery for propaganda in enemy countries was greatly increased, there was a further extension of distribution by balloons. The military successes of the Allies were being concealed from their troops by the Germans, and it was thought that quick and accurate information would further demoralize the Germans. In conference with the War Office, Lord Northcliffe's department arranged that the leaflets should be divided into two categories, "stock leaflets," the contents of which would not deteriorate by a little delay, and "priority leaflets" containing matter of urgent importance. The latter were printed three times a week and sent in editions of 100,000 direct to Messrs. Gamage, who were manufacturing the balloons and the "releases." They were at once prepared for distribution, handed over to the Military Transport Department and sent via Boulogne direct to the distributing stations. In favourable weather they were thus actually in the hands of the Germans 60 hours after being written.

But even with the best arrangements, distribution by balloon is subject to many delays from weather and other conditions. Lord Northcliffe continued to urge on the Cabinet the need of distribution by aeroplane, and was at last successful in breaking down the resistance. The writer of this article, then liaison officer between Lord Northcliffe's department, the Directorate of Military Intelligence and the Air Force, in the second half of 1918 carried through the final stages of the negotiations. The last obstacle was the fear of the Air Ministry that bundles of leaflets suddenly scattered in the air might foul the steering guys of the aeroplanes; he devised a simple mode of packing the leaflets so that they would fall as a solid bundle for 20 ft. before dispersing. On the morning of the Armistice, the first packets of propaganda made up on this system were delivered to the Air Force in France.

The methods of distributing propaganda by the Allies were ascertained in a conference held in August 1918 at Crewe House under the chairmanship of Lord Northcliffe. Aeroplanes were used by the British forces in the Near East, and by the Italians, French and Belgians on the western front. But it was clear that either lack of aeroplanes or of personnel limited their use even by those who had no objection to it. The Italians used special devices such as rockets and shells, the French were experimenting with shells and trench-mortars and were trying to manufacture balloons on the British model, and both the French and Belgians sent large quantities of newspapers and of other matter to be distributed by the British balloons. The Americans had hardly reached the actual stage of distribution before the end of the war, but they had developed a small rubber balloon with a very ingenious timing device for releasing the load. It is a reasonable assumption, however, that all these methods would be replaced by aeroplanes in any later war.

Lord Northcliffe's Directorate.—In Feb. 1918 the Prime Minister appointed Lord Northcliffe to be Director of Propaganda in Enemy Countries. Lord Northcliffe brought to the task a limitless faith in the possibility of controlling public opinion, a unique experience in the methods of publicity, and direct access to the Prime Minister and the War Cabinet. He selected a council of advisors and an executive staff of remarkable authority and talent, and Crewe House, in Mayfair, London, the headquarters of the new Department, quickly became the centre of far-reaching activity. A mere catalogue of the operations undertaken, and of the men who carried them out would occupy many pages.¹ But two names must be mentioned, as without them Crewe House would have been little more than a powerful addition to the existing propagandist agencies. Sir Campbell Stuart, a young Canadian who had been of great assistance to Lord Northcliffe on his mission to the United States of America, was selected as deputy-director of the de-

partment and deputy-chairman of the committee. Lord Northcliffe's choice was fully justified by the remarkable powers of tact and conciliation shown by Stuart, who rapidly dispelled all suspicion on the part of existing organizations, found out how to get the best work out of all of them and how to combine their efforts towards a single resolute purpose. Lord Northcliffe selected Mr. H. Wickham Steed as his chief political adviser. Steed at the time was foreign editor of *The Times*, and for many years had been the representative of that journal in Rome and Vienna. He had an exceptional knowledge of the political personalities of modern Europe, the open policies and the secret aspirations of all the nationalities great or small. He was an idealist, believing that truth and justice could bring ordered peace to chaotic Europe; a realist, conscious of the stubborn obstinacy that would yield only to force and of the ignorance that misled the accepted leaders of men. Steed provided the knowledge and lofty enthusiasm which shaped the policy of Crewe House, Stuart the conciliatory tact which made concerted action possible, Lord Northcliffe the swift judgment between contending views, the experienced instinct for what was practical, and the driving force to make the practical actual. The present writer assisted at many intimate deliberations at Crewe House; he desires to add his own observations to the varying estimates that have been made of Lord Northcliffe. The Director of Propaganda in Enemy Countries was patient in listening to the facts and arguments put before him, decisive in coming to a judgment on them, swift and powerful when action began. Steed's knowledge, Stuart's organizing tact, and Lord Northcliffe's driving force and far-reaching influence, made Crewe House different in quality and energy from any preëxisting agency.

The inspiring principle of the new organization was that propaganda should depend upon policy. It may be argued, although not convincingly, that a definite constructive Allied policy could not have existed in the earlier stages of the war, when fortunes were changing and the nature of the ultimate decision was uncertain. In any case, if a concerted policy did exist, it was unknown to those who were conducting propaganda. The wiser propagandists in most countries therefore endeavoured to limit themselves to a restricted field from which declared "war aims" and ultimate terms of peace were excluded. Rash agents plunged, with results that were often ludicrous and sometimes disastrous. Dr. Lamprecht, the German historian, for example, confessed that the consequences of the German propaganda were often gruesome. Probably, he wrote, more harm came to the German cause from the efforts of the German professors than from all the efforts of the enemy. "None the less it was done with the best intentions. The self-confidence was superb, but the knowledge was lacking. People thought that they could explain the German case without preparation. What was wanted was organization." A single example will illustrate the results of lack of organization amongst the Allies. The French military authorities complained to the War Office that German propaganda appeared to be entering France in large quantities through England. They sent examples, and asked that precautions should be taken. On enquiry it was found that the incriminated documents were the product of one of the British civilian propagandist agencies. Doubtless it was a matter of opinion whether the French or English judgment of the efficacy of the leaflets was the more correct; but the real fault was the absence of harmonious effort. In 1918, the fifth year of the war, it became of vital importance that the Allied peace aims should be explained with a clear and unanimous voice to the war-weary enemy. It was to this purpose that Lord Northcliffe addressed himself. He used his influence first to extract from the British Government the broad lines of a definite policy, in order that the propaganda of his Department might not be in conflict with the casual and sporadic utterances of ministers; next to secure unity of purpose among the British and Allied propagandist agencies.

The first campaign was against Austria-Hungary. The British Government, hampered by the secret Treaty of London, hesi-

¹ *Secrets of Crewe House*, by Sir Campbell Stuart (London, 1920), gives an account of Lord Northcliffe's undertaking.

tated between the policy of working for a separate peace with the Habsburg dynasty, leaving its territory almost untouched, and the alternative of trying to support and encourage all the anti-German and pro-Ally elements in the Austria-Hungarian Empire. The objective selected by Crewe House was to support the national desires of the Czechs, Southern Slavs, Rumanes, Poles and Italians for independence, so as to form a strong non-German chain of Central European and Danubian States, and thus to encourage the disinclination of these peoples to fight for their German masters.

The chief obstacle to the policy of the British propaganda was the pledge given to Italy in 1915, to give her certain Austrian territories inhabited by Southern Slavs. In 1917, the Serbs, Croats and Slovenes had assembled in Corfu, and under the leadership of Dr. Trumbitch, president of the Southern Slav Committee, and M. Pashitch, prime minister of Serbia, had proclaimed the unity of the three Southern Slav peoples. Early in 1918, after recovery from the disaster of Caporetto had begun, the united Southern Slavs, on the initiation of Mr. Wickham Steed and Dr. Seton Watson, came into conference with leading Italians and agreed to settle amicably the territorial controversies in dispute. Lord Northcliffe took up the position at that point, and almost the first step of his campaign was to send Mr. Steed and Dr. Seton Watson to the Congress of Oppressed Habsburg Nationalities which took place at Rome with the consent of the Italian Government. Meantime he urged on the War Cabinet the need of coming to a decision between the alternative policies and of obtaining the agreement of the French, Italians and Americans to the choice. He got only a dubious and halting opinion from the British Foreign Secretary, who urged that the same propaganda could be adapted at least to the earlier stages of either policy. This indecision, maintained through the war and through the peace negotiations, led to the disastrous adventure of D'Annunzio, for the Italians, like other peoples, flushed with the unexpected joy of complete victory, forgot the wise concessions to which they had been willing when the issue was doubtful. But Lord Northcliffe's mission achieved a temporary and successful unity of purpose. A joint commission consisting of representatives of Italy, Great Britain and France, was established at the Italian general headquarters, with the special object of conducting propaganda directed to the oppressed nationalities in the Austrian armies. Representatives of committees of each of the oppressed nationalities were attached to the commission. A polyglot printing press was acquired, and large quantities of propaganda of all kinds were distributed by aeroplane, rockets, grenades and contact patrols. The latter consisted of deserters of Czechoslovak, Southern Slav, Polish and Rumanian nationalities, who volunteered for this service against their former oppressors. The effect was soon apparent. Deserters belonging to the subject races came over to the Italian armies in large numbers, so that the attack planned by the Austrians had to be postponed. Unfortunately, the complete success of the effort, apparently assured early in May, was prevented by the reactionary tendencies within the Italian Government, supported by the uncertain attitude of the Governments of France, Great Britain and the United States. But even in the face of this difficulty, the success was so great that, after the battle of the Piave, members of the Inter-Allied Propaganda Commission were received and thanked by the Italian commander-in-chief.

While this great campaign was taking place on the Italian front, the propaganda addressed to Germany was being intensified. On assuming office, Lord Northcliffe found the War Office propaganda department, described above, in full operation. Except that he at once began to press the Government to renew the original permission for the use of aeroplanes, he suggested no change in the War Office work. His committee at Crewe House, however, first with the assistance of Mr. H. G. Wells and after a few weeks with that of Mr. H. Hamilton Fyfe, set to work to frame a general propaganda policy directed against Germany, and to produce leaflets and other matter. Some of this material was given to the War Office Department; much of

it was distributed by special means chiefly through neutral countries. In July, when the work in Italy had been established on permanent lines, and Mr. Steed had returned to London, it was decided to concentrate all the production of propaganda at Crewe House, with the object of bringing it more into line with a concerted policy. Accordingly, the writer of this article was transferred from the War Office to Crewe House, but kept in touch with the War Office as liaison officer, the army remaining the agent for distribution.

The General Committee met daily at Crewe House, receiving the reports of the different branches, collecting information from all possible sources, and stimulating the propagandist work against Austria-Hungary, Bulgaria and Germany. It became more and more obvious during the summer of 1918 that the spirit of the enemy was breaking on every front, that they were alert to every suggestion as to the approach of peace, and that the supreme necessity was a clear statement of the intentions of the Allies. Lord Northcliffe, with varying success, continued to press the Government for such a definition of policy as would serve as a true basis for propaganda. The fundamental principle on which he wished to act was that when a line of policy had been sanctioned as a basis for propaganda, the Allied Governments should be asked for their assent to it, so that their propaganda departments might act in concert. Failing to obtain a clear lead from the British Government, who at that time appeared to have no definite policy with regard to any issue of the war, Lord Northcliffe convened an inter-Allied propaganda conference at Crewe House. It was attended by Lord Beaverbrook, Minister of Information, representatives of the British Foreign Office, War Office, Admiralty and Air Ministry, and by delegates from France, Italy and the United States, the U.S.A. delegation, however, being instructed to attend only as observers. The conference, after a plenary session, divided into committees to discuss details of policy, methods of publicity and methods of distribution. At a final plenary session the reports of the committees were adopted, and it was agreed that they should be submitted by the heads of the four missions to their respective Governments for approval. The conference then constituted a permanent Inter-Allied Body for the conduct of propaganda in enemy countries. Steps were at once taken to secure the permanency of contact between the propagandist agencies which had been established at the conference, and these became increasingly effective until, when the Armistice came, there was almost complete unity of action amongst the Allies.

As the possibility of peace drew nearer, it became still more urgent that propaganda should be kept free from any trace of confusion. To secure this, a Central Body, called the Policy Committee of the British War Mission, was formed at Crewe House; it consisted of representatives of Lord Northcliffe's department and of the War Cabinet, the Admiralty, War Office, Foreign Office, Treasury, Ministry of Information, Air Ministry, Colonial Office, India Office, War Aims Committee and Official Press Bureau. It decided to undertake the following activities:—Study of peace terms, study of utterances by important enemy representatives, their real significance and the nature of the response to be made to them. It had to take action almost at once, since the German Peace Note, with its reference to the publication of President Wilson's "fourteen points," required immediate attention from British propagandists. Lord Northcliffe's committee had been studying the fourteen points with a very close attention. It was plain that they could not be understood as a full recitation of the conditions of peace, and that it was therefore a matter of honesty and of prudence to define the interpretation put on them by Great Britain before accepting the surrender of Germany. This view was accepted by the Policy Committee, and, after detailed discussion, a statement drafted by the Crewe House Committee was adopted in principle. It was approved, by a representative of the Government designated for the purpose, for unofficial use as propaganda policy. Each department henceforward made it the text of its productions. As this document is of historical interest, it is here printed in full.

Confidential.

PROPAGANDA PEACE POLICY

The following conditions are indisputable:—

In no sense shall restoration or reparation in the case of Belgium be taken into consideration when adjusting any other claims arising from the war.

1. The complete restoration, territorial, economic and political, of Belgium.
2. The freeing of French territory, reconstruction of the invaded Provinces, compensation for all civilian losses and injuries.
3. The restoration to France of Alsace-Lorraine, not as a territorial acquisition or part of a war indemnity, but as reparation for the wrong done in 1871, when the inhabitants of the two Provinces, whose ancestors voluntarily chose French allegiance, were incorporated in Germany against their will.
4. Readjustment of the frontiers of Italy as nearly as possible along the lines of nationality.
5. The assurance to all the peoples of Austria-Hungary of their place amongst the free nations of the world and of their right to enter into union with their kindred beyond the present boundaries of Austria-Hungary.
6. The evacuation of all territory formerly included in the boundaries of the Russian Empire, the annulment of all treaties, contracts or agreements made with subjects, agents or representatives of enemy Powers since the revolution and affecting territory or interests formerly Russian, and coöperation of the Associated Powers in securing conditions under which the various nationalities of the former Empire of Russia shall determine their own form of Government.
7. The formation of an independent Polish State with access to the sea, which State shall include the territories inhabited by predominantly Polish populations, and the indemnification of Poland by the Powers responsible for the havoc wrought.
8. The abrogation of the Treaty of Bucharest, the evacuation and restoration of Rumania, Serbia and Montenegro, the Associated Powers to aid the Balkan States in settling finally the Balkan question on an equitable basis.
9. The removal, so far as is practicable, of Turkish dominion over all non-Turkish peoples.
10. The people of Schleswig shall be free to determine their own allegiance.
11. As reparation for the illegal submarine warfare waged by Germany and Austria-Hungary, these Powers shall be held liable to replace the merchant tonnage belonging to the Associated and neutral nations illegally damaged or destroyed.
12. The appointment of a tribunal before which there shall be brought for impartial justice individuals of any of the belligerents accused of offences against the laws of war or of humanity.
13. The former Colonial possessions of Germany, lost by her in consequence of her illegal aggression against Belgium, shall in no case be returned to Germany.

The following conditions of Peace are negotiable:—

1. The adjustment of claims for damage necessarily arising from the operations of war, and not included amongst the indisputable conditions.
2. The establishment, constitution and conditions of membership of a League of Free Nations for the purpose of preventing future wars and improving international relations.
3. The League of Free Nations shall be inspired by the resolve of the Associated Powers to create a world in which, when the conditions of the Peace have been carried out, there shall be opportunity and security for the legitimate development of all peoples.

The action taken thereon by the Enemy Propaganda Committee at Crewe House was as follows: At their suggestion Lord Northcliffe made it the basis of an address to the United States officers in London on Oct. 22 1918. The Production Department of the Committee got to work on a series of pamphlets and leaflets dealing with the different points of the memorandum. The memorandum was sent to the French, Italian, and American members of the inter-Allied Body for Propaganda in enemy countries, with the request that they should take similar action on it to that taken by the British Policy Committee and bring it up for discussion at the next meeting of the inter-Allied body. Lastly they decided to prepare and give wide publicity to an article covering the whole ground of the memorandum, so that the policy could be presented in the same terms to the British people, to their Allies and to the enemy. The steps taken by Crewe House, and the corresponding action taken by other departments concerned, were reported and approved at a meeting of the Policy Committee at Crewe House on Oct. 28 1918, the last meeting actually held.

Events were moving swiftly, and Crewe House found that there was no time to carry out the original intention of cir-

culating the general statement through one of the more important monthly periodicals. It was therefore decided to ask Lord Northcliffe to give the peace policy the wide and immediate publicity possible by the use of his name and by the sources of distribution at his command. He agreed at once, and so consummated the efforts of British propaganda. On Nov. 4 1918 an article under his name appeared in *The Times* and *The Daily Mail*, *The Paris Daily Mail*, and the leading papers in Canada, Australia, New Zealand, S. Africa, Newfoundland, India, the British Dependencies, the United States of America, S. America, France, Italy, Spain, Switzerland, Holland, Norway, Sweden, Denmark, Japan and elsewhere, and very soon afterwards in Germany. The arrangements for this wide publicity were made personally by Lord Northcliffe, and the cost of cabling was borne by him. The final form of the article was due to him, but its substance represented the unanimous views of his advisory committee, the members of which he had selected, and over whose deliberations he had presided.

ALLIED PROPAGANDA.—The principles and methods of propaganda have been so fully illustrated in the foregoing account of the British effort, that little would be gained by a detailed description of the operations of England's Allies. France went through a history much like that of Great Britain. In the earlier stages of the war, propaganda was conducted by a number of agencies, for the most part in extension of their normal functions. As the war proceeded, concentration and intensification were achieved, ending in the work being placed under the control of a single minister with a large staff. The control of home opinion was less difficult than in England, as it was already in the tradition of the Government to regulate the dissemination of information and of official views. As, however, a considerable part of the French population was in territory occupied by the Germans, there had to be an extensive distribution of propaganda through the army and by secret agents. An intensive campaign was conducted in Alsace and Lorraine, the services of distinguished Alsations of French descent being employed with great success. Neutral opinion was influenced by special missions and by resident agents. Much care was given to French propaganda amongst the Allies. Distinguished civilians of British and American nationality were frequently invited to France, and given every opportunity of seeing the spirit in which France was making her prodigious effort and the enormous difficulties she had to face. French agents kept in close touch with British opinion of every class, and in every part of the Empire, not neglecting Ireland and Quebec. In one respect this branch of French propaganda was more far-seeing than most of the British work; it was not content with the actual problems of the war, but anticipated and prepared for many of the difficulties and possible causes of friction that might arise in the making even of a victorious peace. France early foresaw that, as German colonies were unlikely to be restored to Germany, it would be necessary for France and Britain to be in general agreement with regard to extra-European territories. The French effort to reach the enemy directly was on a smaller scale, but was similar to the work done by the British War Office. By exchange of views and materials a high degree of concord was reached.

Belgium was in the unfortunate position of being able to operate directly only in a very small part of her own territory. By direct effort, and with the willing coöperation of France and Britain, she was able to keep in close contact with her own people. The unmerited calamities which fell on Belgium secured her in advance the sympathy of neutral and Allied nations so that special propaganda was unnecessary. Italy was rather a theatre for propaganda than a direct propagandist. She spoke with so many different voices that, except for a certain amount of direct propaganda addressed to the enemy, she was unable to explain her attitude very clearly either to neutrals or to Allies. On the other hand, she issued a series of magnificent photographic descriptions of her arduous campaigns, which explained well the immense difficulties of military operations on the Italian front, and the brilliant technical methods by which

they were overcome. The Americans devoted the same energy to propaganda as to preparation for actual warfare. Representatives were at once sent to Europe to examine and report on the methods of propaganda employed by the Allies. By Sept. 1918, an American Propaganda Department had been established with branches in London, Paris and near Verdun. Much literature was produced, and its distribution by aeroplane and by balloon had been arranged when the Armistice came.

GERMANY.—It would be difficult to say how far the exaltation of the German spirit in 1914 was due to official inspiration, or how far the long campaign of German intellectuals and industrials, before 1914, for the aggrandizement of Germany, had inspired official opinion. In any event, the outbreak of the war let loose a flood of literature unanimous in sentiment and apparently spontaneous. Professors and pastors, politicians of every section, pan-Germans and socialists were united in proclaiming the necessity of the war and the certainty of victory. But even in these early days there were striking differences of opinion. One school urged that the war was defensive, forced on Germany by the "encircling policy" of her enemies. German militarism was a necessary consequence of a position surrounded by powerful enemies, of the Russian danger, and of English jealousy of her commercial success. As it was difficult to reconcile this theory with the actual German plan of campaign and with the fate of Belgium, much stress was laid on the theme that an offensive was only the best means of defence. When victory came, annexations were to be limited to what might be necessary for future security. Another school proclaimed the historic mission of Germany, her high culture and civilization, the advantage to the world of her victory. The great empires of the past had expanded and developed for selfish ends; Germany wished to free the seas for all the nations, and to open up the world so that all the peoples great or small could develop on their own lines. England, France and Russia had been the great oppressors of smaller nations and races; Germany would liberate them. The unification of Germany had been the first stage in a beneficent process which would lead, first, to a great federation of Middle Europe, and then to a federation of the whole world. A third school expounded a somewhat careful form of the Bernhardt and Treitschke doctrine. The great and expanding German people required land within the German Empire in which the surplus population might find room and yet remain German. Outlet must be found for German talent, organizing capacity, capital, manufactures, and the necessary supplies of raw material must be forthcoming. These objects Germany would have preferred to attain peacefully. But she was a late arrival on the world-scene, and her rapid development had aroused such envy, particularly from England, that her legitimate rights could be secured only by force. Yet a fourth school, relatively small in numbers but of great influence in the navy, army and among the big industrials, appealed directly to cupidity. The riches, natural resources and possibilities of all parts of the world in which German influence could be extended or which Germany could take from her enemies were described elaborately. The growth of the British Empire was displayed in almost affectionate caricature as an accomplishment of successful piracy; England, however, must now disgorge to the younger and stronger pirate. It was an odd but possibly significant circumstance that, in all these diverging views, little attention was paid to the events immediately preceding the various declarations of war.

So far we are dealing with the unofficial home propaganda of Germany. It consisted to a much larger extent than in Great Britain of books and pamphlets, some of which doubtless were subsidized, but most of which apparently were spontaneous. These served also for the German peoples in foreign lands, and were exported in very large quantities, often in their original form, often in translation so as to serve as propaganda for neutrals. It was a characteristic of German self-confidence that they appeared to think that explanations good enough for Germans were good enough for neutrals and even for enemies. But in addition to such private or at least apparently unofficial efforts, there was an official propaganda on a large and highly

organized scale. The German Press was organized for war, with the object not only of influencing home opinion but neutral opinion, directly through the circulation of German papers in Switzerland, Holland, and Scandinavia, and by their effect on foreign editors. Dr. Theodor Wolff, the well-known editor of the *Berliner Tageblatt*, said that "German censorship passed news concerning facts, but forbade discussion of war events or internal politics and of many other subjects." The Government suppressed criticism or the giving of information with regard to the internal conditions of the country. Every two or three days the newspapers received printed orders indicating what they were forbidden to publish, the attitude they were to assume on particular topics, and the articles from other papers they were free to reproduce. Editors were usually allowed to produce their papers without a preliminary examination of the proofs, but transgression of the regulations was followed by prosecution or suspension. One form of punishment was to place a paper on "preventive censorship," under which all proofs had to be submitted, and any matter could be struck out, without, however, removing responsibility for what remained. The *Norddeutsche Allgemeine Zeitung* was a purely official organ, and several other papers, notably the *Kölnische Zeitung* and the *Berliner Lokal-Anzeiger*, were semi-official.

With regard to the Press generally, there were several agencies of direction and inspiration. The Press Department of the Foreign Office issued a regular news-sheet containing the statements and views the propagation of which was desired; it also acted directly on newspaper correspondents. The Admiralty had a very active publicity department, for some time under the direction of Mathias Erzberger and Paul Rohrbach. The Ministry of the Interior had a separate organization and also circulated "tendencious" sheets. The War Press Bureau, controlled by the Higher Command, was the most important propagandist organ. It issued commands to the censorship, laying down the prohibitions and the special attitudes which were circulated through the local authorities, and it had a special foreign section. Moreover, daily Press séances were held by three officials, representing respectively the Foreign Office, the War Office and the Admiralty, at which instructions and directions too delicate to be committed to paper were issued.

German propaganda in neutral countries was officially controlled by a branch of the Foreign Office, the *Zentralstelle für Auslandsdienst*. It issued material for propaganda and propaganda for distribution through the official representatives in foreign countries. Every Germany embassy or legation had at least one organ under its immediate control, sometimes published in German specially for German readers, more often in the language of the country in which it was issued. The material consisted of copies of a special newspaper, the *Nachrichten der Auslandspress*, prepared by the War Press Bureau, a daily paper containing telegrams and notes on current events, and often selected news cuttings issued by the general staff. Another official agency, believed to be directed by the Admiralty, issued an attractive and well-illustrated periodical, the *Kriegs Kronik*, as well as the *Kriegs Nachrichten*, the latter consisting of prepared articles on war subjects and a "Berlin" letter, for the edification of the foreign Press.

In addition there were several highly important private organizations for foreign propaganda. The *Deutscher Ueberseesendienst Transocean* was a syndicate established before the war by big German industrials to supplement and correct the service of the official Wolff Bureau. It issued the daily German wireless, had a special foreign news-service consisting chiefly of selected cuttings from German and foreign newspapers, and a very fine illustrated monthly periodical in five languages—*Der Grosse Krieg in Bildern*. It had an intelligence division which reported on the standing and personality of newspaper editors in every country, and suggested means of influencing them. The *Kriegsausschuss der deutschen Industrie*, formed originally to represent industrialists in their controversies with the Government, became an extensive propagandist chiefly on trade matters. A bureau at Frankfurt-on-Main, partly official, dealt chiefly

with Latin countries. The *Deutsch-Südamerikanisches Institut*, and the *Hamburgischer Ibero-Amerikanischer Verein* were occupied chiefly with Latin and Latin-American countries, and had agents and usually press organs in every country where Spanish or Portuguese is spoken. The Far East was served through the *Ostasiatische Lloyd*, which supplied a distributing centre in Shanghai.

Until the United States of America came into the war, there was a very active German campaign to influence American opinion in favour of Germany. A great part of it was conducted from the German embassy in Washington, and through the German consuls throughout the United States. Much work was done by special missions such as that of Dr. Dernburg, a former Colonial Secretary, and every German bank or trading corporation was a centre of organized effort. A very large number of serious books by well-known German authors were translated into English for American readers. These followed certain main lines. They drew contrasts between the peaceful progress of Germany since her unification, as compared with the violence of other Powers. They represented Germany as being engaged purely in self-defence. They offered veiled threats or bribes to the United States with reference to Japan. They insisted on the moral basis of German culture and civilization. Closely similar lines were followed by many leading Americans of German descent. Perhaps the most effective of these American-Germans was Hugo Münsterberg, professor of psychology at Harvard, who advocated the cause of his natal country with eloquence and apparent moderation. His main point was that the war was really a struggle between Russian barbarism and the western culture of Germany, France taking sides because of Alsace-Lorraine, England because of her commercial rivalry and desire for German colonies. If Germany were beaten, it would be a triumph of Asiatic Russia and of Japan over the culture of Europe and America. It was suggested that the task of America was to give Europe an honourable peace, which she could do only by the strictest neutrality, with a leaning to Germany. Some true Americans also engaged in propaganda in favour of Germany. Some of these, doubtless, were mere hirelings; the better were chiefly persons of standing in the literary, scientific and musical world, who had been much in Germany. Some of the exchange professors were leaders in this work, and very naturally advocated with zeal and knowledge the best side of the German character and the great part Germany had played in the arts and sciences. Still more vocal were the Irish-Americans, who devoted themselves with a malignant bitterness to propaganda against England.

As regards direct German propaganda against the enemy, comparatively little was done, as compared with other combatants, in the distribution of propagandist literature from Germany amongst the actual troops opposed to her. The *Gazette des Ardennes* was the most successful effort. It was a regular newspaper, written in French and often with an illustrated supplement. It was sent into France by balloons, and occasionally by aeroplane, and sometimes gained entrance through a neutral country. It was eagerly sought, as it was baited with genuine information as to French prisoners. Otherwise it consisted of well-arranged propagandist matter of the usual type. The *Continental Times*, written in English, was founded before the war as a genuine newspaper for Americans travelling in Germany and Austria. During the war, probably with the aid of a German subsidy, it developed into a propagandist organ, chiefly anti-English, and almost ludicrous in its exaggerated malevolence. It was freely circulated among English prisoners in German camps, where, fortunately, it was the occasion of a good deal of amusement. The *Russkaya Izvestia*, written in Russian, was distributed to Russian prisoners of war, and to a smaller extent in Russia. It was a competent piece of work, addressed to the task of persuading the Russian peasant that his two chief enemies were England and his own Government, and that the victory of Germany would mean liberation.

Germany's greatest propagandist effort against her enemies was carried out by indirect means. Wherever she thought that

there was opportunity, she endeavoured to excite the discontented subjects of her enemies. She sought to get in touch with Irishmen, Indians, Arabs, Egyptians, Boers, Algerians and Georgians, and with various black races. A special organization of committee in Berlin attended to each of these peoples, and to many others. Where possible, representatives were lured to Berlin, and, if thought useful, were provided with funds. Missions, sometimes accompanied by Germans, were sent wherever they could be sent with safety. On the negative side the effort had some success, and existing discontent was sedulously fomented. But on the positive side there was little gain, for the Germans were seldom able to persuade the actual or tentative rebels that their future position would be any better under the domination of Germany. (P. C. M.)

PROPELLANTS (see 10.83).—A propellant explosive should burn comparatively slowly, and thus allow the use of a suitable charge for the required muzzle velocity without causing a high chamber pressure, and enable the maximum pressure to be kept low while better sustained; it should burn regularly—which depends upon the area of surface exposed to burning—and the rate should be easily capable of regulation; it should be smokeless, without bright flash; it should not give excessive heat during combustion, but be easy of ignition and not leave any solid residue; it should have both chemical and ballistic stability while in storage. The method of manufacture and the proportionate mixture of cordite, the British smokeless propellant (see 7.38), have been very largely controlled by the postulated requirements, particularly as regards keeping qualities.

With cordite manufactured by the methods in vogue before the World War the nitrocellulose used was highly nitrated, necessitating the use of acetone as a solvent. This involved a serious disadvantage in that the supply of the solvent materially governed the output of cordite. The enormous amounts of propellant required and the demand for rapid supply during the war made this disadvantage seriously felt, and thoughts were turned in the direction of discovering some expedients in which a state of lower nitration would render possible the use of some other solvent, which could be more easily obtained, as well as the devising of new methods by which the time expended in manufacture might be materially reduced. At the same time it was postulated that disturbance of the ballistic and heat value of cordite M.D. was not to be incurred.

Experiments resulted in the introduction of a class of cordite known as R.D.B. (Research Department, mixture B.), with which ether-alcohol is used as the solvent. It consists in a percentage composition of nitroglycerine (42%), nitro-cotton (52%), mineral jelly (6%). A larger percentage of nitroglycerine was included in this mixture in order to compensate for the lower nature of nitrocellulose, and a higher proportion of mineral jelly to reduce the higher temperature produced by the extra proportion of nitroglycerine. The appearance of this class of cordite, as compared with cordite M.D., is not so clear, generally warped, with a rougher surface. With this mixture, not only was there the advantage in employing a solvent, of which supply was assured, but also the time required for drying in manufacture was considerably reduced.

Originally, the tubular form was introduced for cordite in order to maintain an equal area of burning surface, and so permit a more equally sustained pressure during combustion. In the form of strips, cordite gives very similar action as in the form of tubes; this form in manufacture and otherwise has other advantages which favoured its use for cartridges. But since, when made up into charges, strip cordite is apt to become packed tight, and so practically form a solid bundle, the result on explosion may not be as desired.

The provision of cellulose for conversion into nitrocellulose depended during the war very largely on the obtainable supplies. In Germany different expedients were tried, amongst them an unsuccessful attempt to use an artificial silk made by dissolving wood-cellulose in suitable solvents. But practically all the nitrocellulose made in that country, during the war, was made from a certain kind of paper, probably from some form of wood-cellulose (see CELLULOSE).

The American service propellant N.C.T. (nitrocellulose tubular) is a soluble nitro-cotton powder gelatinized by ether-alcohol, and containing a small percentage of diphenylamine added to act as a stabilizer. The powder is practically a pure nitrocellulose powder, and consists of nitrocellulose (97%), stabilizer (0.5%), volatile matter (2.5%).

The nitration of the cellulose is similar to the process in the case of cordite, but the drying of the powder is not carried so far, a con-

siderable proportion of the solvent being retained. The stabilizer, being a substance with an affinity for nitrogen dioxide (NO_2), is intended to prevent the free presence of nitrous acid should any decomposition occur. It is claimed for the stabilizer that it at the same time acts as a detector and shows when decomposition is occurring, by means of the resulting discoloration; but this claim does not appear to have been clearly established. The shape of the powder is different from that of cordite. The mixture is extruded through dies, for charges for smaller guns in a tubular form, and for larger guns as a stick with several longitudinal holes; as it is extruded, it is cut into short lengths, the lengths having a proportionate relation to the diameter of the hole in the stick. This shape enables greater ease in making up cartridges than with cordite, requiring merely the weighing of the charge on scales as against cutting lengths of cordite according to size and weight. Nitrocellulose tubular is not so powerful as cordite, and therefore larger charges are required; it is hygroscopic, and consequently, if cartridges become damp, considerable variations in ballistics may result; it is not so stable in storage as cordite. On the other hand, it is more uniform in burning (at a slower rate and with a lower temperature than cordite), and so causes much less erosion in a gun; and, further, the loading temperature has less effect on ballistics than with cordite, and the regularity in worn guns is better. The colour of the grains varies very much and may be buff, brown, dark blue or even nearly black, perhaps owing to slight changes in the stabilizer present; but practically no difference in stability has been detected, except when the colour becomes brick-red, or rusty, when it may be concluded that corrosion has set in.

A flameless powder has been made in America for which it is claimed that, with field guns firing this kind of powder, it is possible for the eyes of the gunner to see the muzzle of the gun at the moment of firing, and that the flash is imperceptible at a distance of a mile. The composition of the American powder is approximately 60% of nitro-cotton, stabilized only with potassium carbonate, 25-28% of nitroglycerine treated in the same way, 5-7% of diphenylphthalic diethyl ester of the phthalic acid obtained by esterifying phthalic anhydride with ethyl-alcohol in the presence of sodium bisulphate and 3-5% of neutral potassium tartrate; vaseline or mineral jelly up to 5% is used to balance the composition. The dimensions of the powder-sticks and the exact composition depend upon the form to be used and have to be calculated.

The German propellant used with the 77-mm. gun was in the form of tubular sticks, and was a ballistite containing a stabilizer of "centralite" type, the stabilizer being the thio-urea derivative corresponding to diphenyldimethyl-urea. This last substance has been found frequently in German powders; it is very resistant to the action of acids and alkalis and is oxidized by fuming nitric acid only after prolonged heating at a high temperature.

A ballistite containing 60% of nitrocellulose and 38% of nitroglycerine has been used by the Germans; and also a mixture of nitrocellulose (66.16%), nitroglycerine (25.97%), sym. diethyl-diphenyl-urea (5.64%), volatile matter (0.91%), mineral matter (1.32%). With certain guns the Germans tried a mixture of ammonium nitrate (84.5%), carbon (15.0%), ammonium chloride (0.5%), in a compressed block, in the shape of an annulus, which was inserted in the cartridge-case above a charge of ordinary nitrocellulose powder. What was the exact result of this combination is not clear.

Among sporting powders which were tried during the war as propellants might be quoted as an example E.C.3—a powder made by a private company—which was used rather largely in trench warfare. This also is a nitrocellulose powder, which after forming to required shape is treated with acetone so that the outer surface is hardened. It is claimed for this process that the pressure during burning is more evenly distributed and more regularly maintained, since the hardened skin of the powder allows of slow burning to commence with and the porous interior allows more rapid action later on. (F. M. R.)

PROTHERO, SIR GEORGE WALTER (1848—), English man of letters, was born in Wilts. Oct. 14 1848. Educated at Eton, King's College, Cambridge, and the university of Bonn, he became fellow of King's College, Cambridge, and was history lecturer there from 1876 to 1894, when he became professor of history at the university of Edinburgh 1894-9. He was a member of the Royal Commission for Ecclesiastical Discipline 1904-6. In 1899 he succeeded his brother Rowland (afterwards Lord Ernle) as editor of the *Quarterly Review*. He was also editor of the *Cambridge Historical Series* and co-editor of the *Cambridge Modern History*. During the World War he was head of the historical section of the British Foreign Office, and in that capacity attended the Peace Conference in Paris (1919). He was created K.B.E. in 1920. Amongst his publications are *Life and Times of Simon de Montfort* (1877), *Memoir of Henry Bradshaw* (1889), and various volumes of historical papers, as well as the *British History Reader* (1898).

PROTOPOPOV, ALEXANDER DMITRIEVICH (1864-1918), Russian statesman, was born in 1864 and educated in a military school. He served for some time in the army, but he soon left the service and went into business. As a big landowner of the Simbirsk province he took an active part in the Zemstvo life and was elected member of the executive board of the Simbirsk Zemstvo and marshal of the nobility of the Simbirsk province. In 1907 he was elected member of the third and subsequently of the fourth State Duma, where he joined the left wing of the Octobrist (Moderate Liberal) party. Later he became vice-president of the State Duma. The first unfavourable rumours with reference to him arose in connexion with an interview with Herr Max Warburg, the German financier at Stockholm. In March 1916 he visited the capitals of western Europe as one of the leaders of the Russian parliamentary delegation. On his return journey he privately met at Stockholm Herr Warburg, the head of the Scandinavian section of the German Committee on Food Supplies. The importance of the conversation was, however, greatly exaggerated by the press, and also by Protopopov himself. At the beginning of Oct. 1916 Protopopov was appointed, through the influence of the Emperor, Minister of the Interior, in succession to Khvostov, and thus entered the Sturmer Cabinet. A former leader of Liberals, he proved to be now the strongest upholder of reaction. He enforced the censorship with unexampled rigour, and his interference with the food-supply work of the Zemstvos and Towns Union created a serious danger to the activities of these organizations. At a stormy meeting held at the Duma he was asked by his political friends to resign his post, and when he refused to do so they struck his name off the list of members of the party. Hated by the Liberal circles and the Duma, Protopopov not only supported the reactionary policy of Sturmer and Prince Galitzin with the utmost energy, but he is said also to have been one of the secret organizers of the disturbances of Feb. 1917, which he proposed to suppress by military force, and which, unexpectedly for him, resulted in the overthrow of the Empire and of himself. He was arrested by the Provisional Government and committed for trial. He remained for many months in the Peter and Paul fortress and was executed by order of the Extraordinary Commission in Sept. 1918.

PROTOZOOLOGY (see 22. 479) is that branch of zoology which is concerned with the group of animals known as the Protozoa. It is not, as its name might seem to imply, a primitive form of zoology. As a science it is comparatively young, but, owing chiefly to the practical importance of some of the animals with which it deals, it had in 1921 already become one of the largest and most cultivated fields in biology. The Protozoa are very interesting animals, from both the practical and the theoretical standpoint. Nevertheless, they are all small, and most of them of microscopic dimensions. To the general public they are therefore invisible, and consequently unknown, except by the conspicuous results—such as diseases—which they occasionally produce. In common speech they are still nameless, though they are popularly included among "animalcules" and "microbes." But these are unscientific and unnatural groups, which comprise all microscopic creatures, both animals and plants; and consequently the Protozoa are still confused, in the popular mind, with other "microbes," such as the Bacteria, with which they have no connexion.

It will be evident that protozoology, as an independent science, must necessarily have arisen as a comparatively late offshoot of zoology. Its history is bound up with that of the microscope, an instrument which bears much the same relation to protozoology that the telescope does to astronomy. Before microscopes were invented no Protozoa could have been clearly visible. With the first lenses, the largest and most conspicuous of them were discovered; and as microscopes were improved, more and more minute creatures gradually became known. Out of the confusion of forms which the microscope has continued to reveal, the Protozoa have ultimately emerged as a well-defined group of animals, and, as a result, those who study these animals have slowly built up a new section of zoological science.

As an individual science protozoology only became self-conscious at a quite recent period. The name itself, though already in use between 1870 and 1880, only became current after the opening of the 20th century—that is to say, within the memory of many living zoologists. But the science was really born—though not baptized—when the first Protozoa were discovered. This far-reaching discovery was made in the latter half of the 17th century. It was made by a man who was neither zoologist nor physician, but who occupied the humble position of chamberlain to the sheriffs of the little town of Delft, in Holland—Antony van Leeuwenhoek (1632-1723), an amateur microscopist, who studied at no university, nor under any of the great professors of his day, but whose title to fame rests upon the simple and honest application of his own native genius. This remarkable man made his own microscopes, lenses and all, and turned them upon almost every object which suggested itself to his quick imagination. In the course of his work he examined the water from the leaden gutters of his house, from the well in his courtyard, and also fresh rain-water, snow-water and “the water wherein pepper had lain infused.” He found that all these liquids, and many others, were not clear and empty when viewed by the microscope, but teeming with living creatures. The discovery was promptly communicated by letter to the Royal Society in London, who published a part of it in the year 1677. Some of the animals which Leeuwenhoek here described can now be identified as Protozoa, and his letter may therefore be regarded as the first page in the history of protozoology.

Leeuwenhoek, the father of protozoology, himself studied and described many Protozoa. His observations were soon repeated and confirmed by others, notably by some of the early Fellows of the Royal Society and his fellow-countryman Huygens, the great astronomer. But for many years protozoology made little progress, and remained essentially what it was originally, an amusement rather than a science. Although many good observations were made and recorded, they were always disjointed, and often distorted by fancy and speculation. Many good zoologists regarded with doubt and misgiving everything seen with the microscope, an attitude of mind which has not quite disappeared even in these days of perfect instruments. Even the great Linnaeus (1707-1778), who attempted to catalogue and classify all animals and plants, and thereby founded modern systematic biology, never really overcame his suspicions sufficiently to incorporate the Protozoa firmly in his system. His mental attitude is shown in the name “*Chaos infusorium*,” with which, in 1767, he dubbed a mixed lot of questionable protozoal organisms—the term *Chaos* itself having been suggested, no doubt, by Ovid’s “*rudis indigestaque moles*.”

But already at this period many workers were convinced that the Protozoa—or “*Infusoria*,” as they were then called, from their occurrence in infusions—have a real existence. The once notorious John Hill (1716-1775), in the course of his journalistic, theatrical, medical, and botanical adventures, turned his attention to microscopes; and in 1752 he described and, for the first time, scientifically named, a number of Protozoa which he had seen in infusions. Up to this time writers had been content to call them by diminutives of the names of larger and more familiar creatures, or occasionally by names suggested by comparison with some common object. We thus find the early protozoologists describing their observations upon “little insects,” “worms,” “fishes,” and even “reptiles,” and upon “the slipper,” “the sun,” “the trumpet,” “the gimlet,” or “the bell animalcule.” It was not until 1773 that a serious attempt was made to reduce the chaos to order by careful observation and description and classification of the “*Infusoria*.” This notable work was done by the Danish naturalist, O. F. Müller (1730-1784); and his last book, published posthumously in 1786, is the first systematic treatise on protozoology. It is a remarkable work, full of shrewd observations, and showing astonishing insight, but containing, of course, many mistakes which were inevitable at that period. Many of the Protozoa described and sketched by Müller—mostly from observations made, as were those of Leeuwenhoek, with the aid of only a simple lens—are easily recognizable now by a protozoologist.

The circumstance that Müller was able to attempt a comprehensive systematic treatise on the Protozoa implies that a very considerable advance had taken place in biological thought since microscopic organisms were discovered. Many of the earlier workers, like the uneducated at the present day, believed in spontaneous generation. They believed, with Aristotle, that many “imperfect” animals were bred in mud, water, or decomposing matter; and so long as this view was tenable there was no reason why these misbegotten offspring of the superabundant vitality of the earth should display any particular constancy in their appearance or any fixity of form. Consequently, to attempt to describe and classify the “*Infusoria*” must have seemed a futile task to many men of science two hundred years ago.

Spontaneous generation, as a scientific doctrine, was not really demolished by the admirable experiments of Redi (1668), as is often supposed, for he disproved it for only the larger and more obvious animals, such as insects; and the later discovery of microscopic organisms raised the whole problem once more, but presented it in a much more difficult form. It was Redi’s countryman, Spallanzani, who, a hundred years later, extended his observations to microscopic animals, and showed by means of ingenious and exact experiments that the “*Infusoria*” spring from living antecedents, and live, grow, and multiply like larger creatures. Spallanzani helped to lay the foundations on which Müller built, though his own work was not firmly consolidated until, a century later, the last rivets were driven in by Pasteur and Tyndall.

In the latter half of the 18th century many minor contributions were made to protozoology, and although these were continued during the early part of the next century, no considerable advance was made until about 1830, when the Berlin zoologist, C. G. Ehrenberg (1795-1876), began to publish his researches. With amazing perseverance he studied, described, and named all the “*Infusoria*” that he could find; and as he pursued his investigations not only at home, but also in Egypt, Arabia, Siberia, and elsewhere, the forms which he discovered were not a few. His chief contribution to protozoology was published in 1838—a monumental folio volume of more than 550 pages, accompanied by an atlas of 64 coloured plates. This is still one of the classics of the science. It contained much that was new and much that was true, everything of note that his industrious reading could find in the works of his predecessors, and without a mass of mistakes, to which he clung tenaciously—in spite of violent contradiction and criticism—to the end of his days.

Ehrenberg’s most dangerous opponent was a Frenchman, Félix Dujardin (1801-1860). In 1841, with an octavo volume of some 680 pages, but only 23 plates, he undermined the foundations of the big folio, and thus overthrew, for all time, many of the favourite theories of his German antagonist. Dujardin’s work is also a protozoological classic. Together with Ehrenberg’s volume it marks the end of the old protozoology of the micrographers and the beginning of the new science as a special branch of zoology. Rarely does the modern worker, unless he be a historian, require to consult any earlier treatises than these.

Since the time of Dujardin only one really exhaustive work on the Protozoa as a whole has been written. This is the great monograph by O. Bütschli, of Heidelberg, published in 1880-9. It is significant of the vast modern development of protozoology that up to 1921 no work on a like scale, by a single individual, had been produced. It is now, indeed, impossible for any one man even to read all that has been written on the Protozoa, and the more recent workers have had perforce to devote their attention to some particular group of these organisms, or to some special branch of protozoology. To master a detail of the science is now the work of a lifetime. No one man could in 1921 claim to be an expert in all protozoology any more than in all mathematics or all chemistry. The territory already surveyed was so vast that the most he could hope to do was to cultivate his own small holding properly.

The Modern Science.—Since the middle of the 19th century biological theory and practice have undergone profound changes; and in more recent years protozoology, with the rest of zoology, has largely changed its character. This period has seen—to note but a few of its more striking developments—the establishment of the Theory of Organic Evolution, the rise of the Cell Theory, the foundation of Histology and Cytology, and the unfolding of Physiology and Embryology and Medicine as experimental sciences. Protozoology has been profoundly influenced by all these new growths, and has itself contributed not a little to them. An attempt has been made, and has already been partly successful, first, to discover all the Protozoa there are, both living and fossil; then to investigate their structure in the minutest detail, and to ascertain how they live and develop; and finally, to understand their relations to other organisms and their place in nature. Countless monographs have been written on individual species, on the larger and smaller groups into which these can be scientifically classified, on collections made all over the world, and upon the special physiological, medical, and other problems which the Protozoa, as a whole or in part, present. But we must content ourselves here with the merest sketch of the growth and status of modern protozoology.

Before proceeding, we must note some of the peculiar difficulties which differentiate protozoology from the rest of zoology. The animals with which it deals are, speaking generally, invisible to the naked eye. Consequently, they cannot be studied and anatomized by ordinary methods. The protozoologist has first to become a master in the use of the microscope, and to learn its limitations as an instrument of research. When he

has become proficient he must learn or devise methods for catching, watching, breeding and preserving those Protozoa that he wishes to study, and must thus become familiar with a peculiar and varied technique adapted to the investigation of the lives and habits of animals invisible to the unaided eye. He must then acquire the power of correctly interpreting what he sees under these peculiar conditions. If he is an efficient microscopist and a good observer, endowed with abundant patience and ingenuity, and if, at the same time, he is a good zoologist and sound philosopher, then, with experience and diligence, he may hope some day to become a good protozoologist. From the very nature of the subject, therefore, it will be obvious that it is easier to make mistakes in protozoology than in most other branches of zoology; and there can be little doubt that the writings on the Protozoa, taken as a whole, contain a larger percentage of error than those on any other group of animals. Protozoology is, indeed, still in its infancy, and learning slowly and painfully by the method of making mistakes.

Protozoology, like most other sciences, is important from two different standpoints, which may be called the theoretical and the practical. On the theoretical side we have to consider its relations to the rest of zoology, and the value of its contributions to biological philosophy; on the other side, we must consider the utility of its practical applications, which are chiefly medical. In other words, we must look at protozoology as a pure science and as an applied science. It is necessary to distinguish these two aspects, although they are inextricably blended in reality. Protozoology was actually applied in medicine before it was ready; and this led not only to great confusion but almost to the severance of Medical Protozoology from the rest of the science. But progress on the medical side has now reacted beneficially upon the pure science, by bringing to light many new facts and setting many new problems.

The Pure Science.—The theoretical importance of protozoology is not what it appeared to be fifty years ago. It has not fulfilled some of the high hopes then entertained for its future. In the earlier period the writer of an article such as this would have begun, in all probability, by declaring that the study of the Protozoa would lead to the solution of most of the outstanding general problems of biology. He would have pointed out that these animals were of the greatest importance in connexion with the two chief biological generalizations of his time—the Cell Theory and the Evolution Theory—and he would probably have ended by saying that it was only lack of detailed knowledge which prevented protozoology from answering most of the fundamental questions of biology. Yet we have now an abundance of the sort of information then regarded as requisite, and the great problems are still, for the most part, where they were. It is both interesting and instructive to inquire how this has come about.

The cell theory was first definitely formulated, in Germany, by Schleiden (1838) and Schwann (1839), and was modelled into its modern form by Max Schultze (1861): that is to say, it took shape at the time of the reformation of protozoology by Ehrenberg and Dujardin, when the science was still feeling for a foothold. According to the cell doctrine, all organisms, both animals and plants, are built up of structural units, called "cells," in much the same way as a house is built of bricks. Schultze defined "a cell" as "a little lump of protoplasm with a nucleus inside it," and this definition was generally accepted. It should be noted that this proposition, so far as the larger animals and plants are concerned, is not a "theory" at all, but a statement of fact easily verifiable by means of the microscope. The body of a rabbit or a cabbage is, for the most part, actually composed of "cells" as conceived in the definition. The "theory" was introduced when the proposition was held to apply to all organisms at all stages in their development. Dujardin had shown that the Protozoa are soft-bodied animals composed of "sarcode"—the "protoplasm" of later workers—in which no constituent "cells" are discernible. Like "cells" Protozoa contain "nuclei," but, unlike the large animals, they show no internal differentiation into cellular units. It was thus

necessary to introduce some new conception if the cell theory was to become universally applicable.

The extension of the theory, so as to enable it to include the Protozoa, was made by von Siebold. Each individual protozoon, he said, is itself a "cell." It is comparable with a single one of the innumerable units of which the bodies of large animals are built. The Protozoa are "unicellular" animals, all others "multicellular." According to this doctrine, therefore, a protozoon is not comparable, as an individual, with a whole multicellular animal, but with one of the cells in its body: or, the other way about, a multicellular animal is not an individual of the same sort as a protozoon, but a colony of such individuals.

This conception appeared so plausible—owing, it must be supposed, to the backward state of protozoology and cytology at that date—that it found ready acceptance; and, in spite of the cogent objections which have been raised against it by Huxley (1853), Whitman (1893), Sedgwick (1894), Dobell (1911), and others, it has prevailed down to the present day. The cell theory is still taught to almost every beginner in biology. He is still told that he is not an individual, but a community of individuals; and that the protozoon, which he can see with his own eyes leading an individual existence, is not an individual—such as he believed himself to be—but the equivalent of one little bit of his body.

When the cell theory was being founded, another great biological generalization was just emerging—the doctrine of Organic Evolution. Charles Darwin's great work, which appeared in 1859, created a revolution in biological thinking. Although Darwin's own work, and his statement of the theory, appear to be unexceptionable, the doctrine misnamed "Darwinism" developed along extravagant lines—chiefly, as is now evident, owing to the wild speculations and dominating influence of E. Haeckel and other German writers. The "cell theory" was immediately subpoenaed to give evidence for these "Darwinists." They wrongly believed that the evolution theory required the presence of some "most primitive" and "elementary" animals—from which all the "higher" forms had been derived—on the earth at the present day; and the shaky syllables let fall by the cell theory were eagerly seized upon, interpreted, and ultimately incorporated as incontrovertible facts in the case of the "Evolutionists." "Unicellular" organisms—such as the Protozoa—thus became the starting-point of evolutionary speculations. The Protozoa were obviously the "simplest" animals, since less was known about them than about the others; and they were clearly the "most elementary," each individual representing but one of the structural elements of which the others were composed. Their insignificant size made them the "lowest" forms on earth, and their position—according to the "theory"—at the bottom of the "*Scala Naturae*," made them the "most primitive." It thus became easy to show, by specious arguments and "question-begging epithets," that protozoology occupied a position of fundamental importance in biology. By studying the Protozoa the earliest stages in evolution would be revealed. The beginnings of life would be laid bare. Physiology and morphology would appear in their elemental forms, stripped of all confusing detail. And optimists were not wanting who divined that, by higher and still higher powers of the microscope, Nature's inmost secrets—such as the origin of life itself—would be divulged.

These fantastic dreams have been slowly dispelled by the "dry light" of reason. It has become clear that protozoology was placed in a false position by the devotees of the cell doctrine and the dogmatic evolutionists. Let us look at the fundamental conception of the "unicellularity" of the Protozoa from another angle, and see how it appears in the light of modern knowledge.

In the first place, it is clear that the Protozoa cannot properly be described as "unicellular." Every protozoal animal has an independent existence. It has its own peculiar structure, exercises its own proper functions, leads its own life—often, indeed, a very complex one. As an animal it is, from every standpoint, as much an "individual" as a man is. One protozoon is one whole animal, just as one man is one whole animal. From the

standpoint of common sense, no less than from that of modern zoology, the whole organism is the unit of individuality. But when we examine a protozoon under the microscope we still see—as Dujardin saw—that its body is not differentiated internally into cells, as is that of a man. Its body is often surprisingly complex in structure, but it is never composed of cells. It is clear, therefore, that we can contrast the body of a man with that of a protozoon by saying that the one is cellular in structure, the other *non-cellular*. To call it "unicellular," and thus compare one whole animal with a minute differentiated fraction of another, is obviously absurd. It is as though a man who had only seen houses built of bricks were suddenly to encounter one constructed, all of a piece, of concrete; and then, being unable to find the familiar individual bricks in its fabric, were to declare that the concrete house is not a house—in the sense that the brick house is—but one large and peculiarly modified brick.

When once it is realized that the Protozoa are not, in any sense, "elementary" or "unicellular" animals, but a group of peculiarly constructed creatures, adapted in a special way to particular conditions of life, then it will also be realized that we have no reasons—apart from preconceived ideas derived from unsound generalizations—for believing that they represent "primitive" or "first" forms of life. That they are not "simple" we now know. It is true that they display, on the whole, less visible structural differentiation than most of the larger animals; but physiologically they are very complex. That they are able to perform all the chief functions of "higher" animals, but with fewer instruments, does not make their mechanism easier to understand; and it is thus hardly conceivable that the Protozoa can ever offer us the easiest way of approach to physiological problems. They offer us, indeed, the most difficult field in animal physiology, owing to their microscopic size and *apparent* simplicity of structure. As a great physiologist has well said: "Experience and reflection have shown me that, after all, the physiological world is wise in spending its strength on the study of the higher animals. And for the simple reason that in these, everything being so much more highly differentiated, the clews of the tangles come, so to speak, much more often to the surface, and may be picked up much more readily" (Michael Foster). Attempts to found a "general physiology" on the Protozoa as "cells" and "elements" are doomed to failure, for they are based upon an unsound philosophy; and the speculative and deductive efforts in this direction—such as that of Verwoin in Germany—have slowly given way before the experimental and inductive methods of Jennings and others in America and elsewhere.

As a point of historic interest, it may be noted that the father of protozoology and his immediate followers had none of the extravagant later notions regarding the "unicellular" and "elementary" nature of the Protozoa. For Leeuwenhoek the Protozoa were animals like any other animals, but delightfully and marvellously little; and he thus saw more clearly and naturally than many of his later successors.

There are probably few biologists who now cherish any hopes of seeing the fundamental problems of biology solved by the study of the Protozoa, though the majority still speak and write in the optimistic language of last century. For these mental survivals there is a psychological basis, which seems worth noting before we go on to consider the true status and value of protozoology. There is a curious disposition, apparently inherent in the human mind, to suppose that by studying the most minute creatures we can come nearer to first principles. And it is the same with the study of the larger organisms. As the cytologist probes into the structure of an animal with higher and still higher powers of the microscope, he feels that he is gradually "getting to the bottom" of his problems. He feels that when his microscope has resolved the larger animals into their smallest component parts, and has revealed every detail of the smallest living thing, he will be face to face with fundamentals. It does not require much thought to realize that this is a fallacy. The deeper we delve, the more detail we discover. But it is all of the same sort: we add to the quantity and not to the quality of our

knowledge. With the highest possible magnification we shall obtain no information which is qualitatively or fundamentally different from that to be derived from the study of large organisms, and their gross anatomy, with the naked eye.

The mental bias just mentioned seems to be responsible for many popular—and not a few "scientific"—notions about the Protozoa. It appears, for example, to be at the back of the unreasonable but common belief that the Protozoa are "elementary" and "primitive" animals. Although few biologists now believe in spontaneous generation, yet many are able to believe that living things must have been spontaneously generated from lifeless matter in the past; and to these who hold this belief it still appears self-evident that the organisms so generated were microscopic. Consequently, these biologists feel that the Protozoa must, in some way, be nearer than other animals to "the beginnings of life," and they find no difficulty in conceiving that the first animals were "Protozoa." In the same way, when these same biologists come to consider evolution, and the relations of living animals to one another, they find in the Protozoa the easiest starting-point for their speculations. The Protozoa are "the simplest" animals, and the human mind works most readily from simple to complex conceptions. Consequently, evolution is pictured as necessarily moving in the same direction—the simply constructed creatures coming first, and the complex developing from them. But it is surely a poor philosophy which would constrain Nature to order her infinite events in that particular sequence in which thoughts happen to follow one another most easily in the mind of man.

What, then, it may be asked, is the theoretical interest or value of protozoology? Clearly it is this. Biological theory is sound in proportion to the truth of its generalizations. When all the facts are known about all animals and plants, we shall be able to make true general propositions about them. Before we know the facts our generalizations can be but partial and premature—more or less lucky guesses, based upon incomplete knowledge. All biological theory is at present in this condition and therefore the careful study of any animal or group of animals—such as the Protozoa—will, if it yields new facts for generalization, be valuable ultimately as a contribution to biology. At present we cannot hope to do much more than collect facts, by means of accurate observation and apposite experiment. When we have collected and critically analyzed them, we can sometimes make tentative generalizations of a lesser order. But the larger and truer generalizations will come later.

It may be said that if this is all that can be expected from protozoology, then it is no more important than any other branch of zoology: there is no reason why we should study the Protozoa rather than any other group of animals. All this is quite true and reasonable; but there is also a reason why protozoology is likely to yield results of particular interest. The Protozoa are a group of animals organized on a different principle from the rest. They are, as we have just seen, non-cellular animals with peculiar lives and habits. Structurally and functionally they differ, in many ways, from all other animals. Now all the chief biological generalizations—almost all general propositions relating to such phenomena as birth, growth, development, sex, reproduction, heredity, variation, and death—have been derived from observations made upon the larger multicellular animals. When general ideas were formulated on such subjects the Protozoa were practically left out of account. When the more important facts about the Protozoa are firmly established, we shall be able to recast many of our biological theorems in a more satisfactory form. The Protozoa offer us, in other words, a new world of animals for generalization, and a new standpoint from which to survey our old-world zoological knowledge. The discovery of the Protozoa was to zoology what the discovery of America was to geography. But we are still, in protozoology, in the 16th century. For our knowledge of the new world we must still depend upon travellers' tales, upon reports of things ill-observed and misunderstood, marvels and myths and mysteries. But some day we shall have accurate and faithful records, and then protozoology will come

into its own. As yet we are hardly on the threshold of the new biology, but for those who delight in the destruction of error and the advancement of true learning, the protozoological prospect is already full of hope.

The Applied Science.—The chief practical applications of protozoology are to medicine. Certain of the Protozoa live as parasites in the bodies of men and animals, and thereby cause diseases. Some of these are so important that they are widely known—for example, malaria and sleeping sickness—and the elucidation of such diseases is one of the most interesting and recent chapters in biology. Protozoology also has certain applications to agricultural science, because many Protozoa inhabit the soil, but their value is still doubtful.

The founder of protozoology was the first to find Protozoa inhabiting the living bodies of other and larger animals. In 1681 he described one such "animalcule" which was living in his own intestine. In 1683 he described and depicted others from the intestine of the frog. All these are recognizable, with fair certainty, at the present day. Leeuwenhoek did not suggest that these "parasites" were in any way concerned in the causation of disease, and it is probable, indeed, that the forms which he observed are not. But already at that date the "microbe" theory of disease-production was in existence, for it was guessed at long before any "microbes" were discovered; and consequently we find that, even in Leeuwenhoek's lifetime, the suggestion was put forward that his "little animals" might be the "causes" of certain disorders. We find, for example, an early fellow of the Royal Society remarking, in 1683, of a "murren" which had raged among the cattle in central Europe, and of which the cause was undiscovered: "I wish Mr. Leeuwenhoek had been present at some of the dissections of these infected Animals, I am persuaded He would have discovered some strange Insect or other in them." Mr. Leeuwenhoek's successors have, on many a like occasion, fulfilled the expectations of "the ingenious Fred. Slare, M.D., and F.R.S.," but his "strange insects" they now call "Protozoa" or "Bacteria."

From the time of Leeuwenhoek to the present day the parasitic Protozoa have been studied with increasing attention. Their relation to diseases has been gradually elucidated, though we are still very far from finality in our knowledge of this absorbingly interesting subject. The history of our knowledge is long, and the discoveries have followed devious ways—too devious and intricate to be more than touched upon here.

Our knowledge of protozoal diseases—diseases colloquially said to be "caused" by protozoal parasites—really begins as recently as the middle of the 19th century, when Louis Pasteur (1822-1895) began his researches on a disease of silkworms called *pébrine*. Applying to the investigation of this disease the genius which stamps his work on "microbes" generally, Pasteur first discovered its causes, and then deduced methods for its prevention. The "cause" he found to be a microscopic parasite, now called *Nosema bombycis* and classified among the Protozoa. Although Pasteur did not know that the parasite was a protozoon, his work on *pébrine* and other microbic diseases was of fundamental importance for protozoology, because it demonstrated the methods by which such diseases can be studied and elucidated. Pasteur's scientific principles were impeccable, and equalled only by his own practical applications of them. It is common knowledge that he founded modern bacteriology; but in so doing he also laid the foundations of medical protozoology. To the casual reader it may seem strange that the study of silkworms can have any bearing upon medicine, or could in any way contribute towards the alleviation of human suffering. But there was another practical result of Pasteur's work which everyone will immediately appreciate, since it can be expressed in pounds, shillings and pence. Before *pébrine* attacked the silkworms of France the silk industry yielded an annual revenue of 130,000,000 francs to the State. After the disease had raged for a dozen years the revenue had fallen to 8,000,000, and the industry was on the brink of ruin. To have discovered the causes of the disease, and to have devised, as a direct consequence, means for its control, and, as a further consequence of this, to

have rehabilitated the whole silk industry—these are practical results which everyone can understand. And one has but to remember that protozoal diseases may affect man himself and his larger domesticated animals—not merely silkworms—to realize the practical possibilities of protozoology.

Towards the close of the 19th century medical protozoology became linked up with another branch of zoology—entomology, the science which deals with insects. This connexion has nothing to do with the silkworms just mentioned, but arose through the discovery of the part played by certain other insects in the causation of protozoal diseases. The discoveries in this field began, once more, with the investigation of a disease of domesticated animals; but the pioneer was not, in this case, the Frenchman Pasteur, but the Scotsman David Bruce. His work is of such importance that we must notice it at this point.

The Work of Bruce.—Some parts of Africa are the home of certain large blood-sucking flies called "tsetse." The "Fly Country" is uninhabitable except for wild animals; and long before its full significance was understood, the fly itself was recognized as a serious obstacle to the opening-up of Central Africa. Livingstone, the greatest of all African explorers, was so impressed with the fly's importance in this connexion that he put a vignette of a tsetse on the title-page of his *Missionary Travels* (1st ed., 1857). Live stock taken into the "Fly Country" rapidly succumbs to a disease which is called "nagana" in Zululand, where Bruce's original investigations were made. The disease was also called "tsetse-fly disease," since it was believed by the European settlers to be caused by the bite of the fly. The natives believed, however, that it was "caused by the presence of large game, the wild animals in some way contaminating the grass or drinking-water."

Bruce began his work in Zululand—after an abortive attempt in 1894—in Sept. 1895 (the month of Pasteur's death). His full report on his researches is dated May 1896. In this almost incredibly short space of time he demonstrated that nagana is caused by a protozoal blood-parasite—since named *Trypanosoma brucei*, after its discoverer; that the parasite lives normally in the blood of big game, without harming them; and that it is conveyed from animal to animal by the tsetse. When the fly sucks the blood of an infected animal it becomes itself infected with the trypanosomes, which are subsequently re-inoculated into other animals by the fly when it sucks their blood. If these other animals are domestic stock, such as oxen or horses, they become infected with trypanosomes, contract nagana, and die. If they are wild game, such as antelopes, they also become infected, but develop no disease. In nature the trypanosome lives in the game and the flies alternately, the fly acting as an intermediary in the spread of infection from antelope to antelope. The big game—indigenous in the country—are habituated to and proof against the infection; domestic animals—foreigners, introduced by man—are not, and when infected usually die.

Bruce thus succeeded in extracting elements of truth from both the European and the native beliefs, and was able to combine them into a true theory of the causation of nagana. At the same time he threw a flood of light on many other protozoal diseases, and suggested all sorts of possibilities concerning their causation and prevention. He forged new links between protozoology and medicine and between entomology and protozoology. It is true there were other lights and other links before. Trypanosomes were known, and known to cause diseases, before Bruce went to Zululand. Timothy Lewis and Griffith Evans had observed similar parasites in India more than a decade earlier; and Theobald Smith and Kilborne, in America, had demonstrated in 1893 that the disease of cattle known as "Texas fever"—a disease also caused by a blood-inhabiting protozoal parasite—is transmitted from beast to beast by the agency of ticks. But Bruce's work was solid, complete, and demonstrative. By clean experiments and right reasoning he contributed more to science in a few months than hundreds who have followed up his work have since been able to contribute in many years. In work of this sort it is the quality, not the quantity, that counts. Later researches have but served to enhance the

magnitude and difficulty of the problem which confronted Bruce in 1895; and to find a just parallel to the masterly manner in which he solved it, we must go back to Pasteur. There is, indeed, the same simplicity, the same directness, the same insight in the work of both these men. Their works are enduring demonstrations of the method of science: they are a delight to read, and illustrate on every page the favourite maxim of Boerhaave: *Simplex sigillum veri*.

The following-up of Bruce's discoveries and the working-out of details and consequences have led to the accumulation of an immense amount of new knowledge—protozoological, entomological, and medical. We can do no more than mention it here. We must, however, notice one of the first-fruits of his labours—the application of his results to the study of human diseases. This application was made mainly by Bruce himself. A few years after he had done his great work on nagana he attacked the problem of sleeping sickness, a human disease which has depopulated large areas of Central Africa. Bruce and his collaborators were able to show that this disease is similar to nagana. It is likewise caused by a trypanosome, which is conveyed to man by the bite of a tsetse-fly, and which is capable of living in other animals. In this case the parasite had been previously seen by Forde and Dutton, and by Castellani. But its relation to human disease and the part played by the tsetse in its transmission were first clearly demonstrated through the work of Bruce.

Malaria and Other Diseases.—We must now notice another disease, which is known by name to all—malaria, “the scourge of the tropics.” This disease, as we now know, is also carried from man to man by the agency of a blood-sucking fly—in this case a mosquito, and it is also caused by a blood-inhabiting protozoal parasite, though it is one very different from that which causes nagana. Moreover, this parasite lives in men and mosquitoes only. After undergoing a peculiar development in the blood of a human being, it is sucked up with his blood by a mosquito when it feeds upon him. Provided that the mosquito is of the right sort, the parasites in the blood—if they are in the proper stage of development—undergo further remarkable changes in the mosquito's body. Thereafter the mosquito is able to infect other men with the parasites, which it injects into their blood in the process of sucking. And so the life of the parasite continues.

The foregoing is the briefest synopsis of a very complicated story, in which almost every event has been worked out in great detail. Hundreds have contributed to this work, though some of them can hardly be said to have coöperated in it. Indeed, such bitter fights have taken place among them that it has now become almost impossible to mention the names of some workers without offending others. The history of these discoveries would give an unpleasant shock to anybody simple enough to believe that men of science always labour for truth and the advancement of knowledge rather than for fame and personal gain. Fortunately the names of the leading discoverers are now known to almost everybody, and their individual achievements are no longer in dispute. Even the “general reader” is familiar with the name of Laveran, the great Frenchman who, in 1880, discovered the malarial parasites in human blood; of Patrick Manson, the founder of modern tropical medicine, who divined, in 1894, the part played by the mosquito; of Ronald Ross, who, inspired by Manson, first worked out in 1898 the complete development of the malarial parasite of birds, and thus solved the general problem; and of Grassi and his fellow-workers in Italy, who immediately confirmed Ross's work and extended and successfully applied his results to the study of malaria in man. When the 19th century ended the story was almost complete.

It will be evident that malaria, nagana, and similar diseases are not purely protozoological problems. It will also be obvious that such diseases might be stamped out and prevented by attacking either the protozoal parasites which “cause” them, or the insects which transmit them, though there could have been but little hope of success in coping with such diseases before the life-histories of the parasites were discovered. When

protozoology, entomology and medicine have solved their respective parts of such problems, then many tropical regions which are now forbidden ground will become habitable for man and beast. The practical importance of protozoology in cases such as these is self-evident. The facts speak for themselves.

Malaria is a far commoner disease than nagana, and the discoveries relating to it have therefore made a far wider appeal to the public. It intrigues the public to hear that there would still be no Panama Canal but for the great discoveries in connexion with malaria. It would excite them but little to hear that some obscure tribe of Zulus could now keep cattle in places where it was previously impossible. But the advancement of science is not measured in such terms, and science values most highly those who discover and enunciate new principles. Already we can observe that the problems presented by nagana and malaria are similar, and that most of the generalizations which their solution can give us are, indeed, the same. We can see, too, that history, in the end, is generally just. Consequently, we may hazard a guess that in years to come the historian of science, in his impartial search for beginnings and great names, will not fail to note the sequence of the discoveries which we have just considered, and will apportion his praise accordingly.

The World War Period.—Medical protozoology, like many another branch of science, received a powerful stimulus from the World War of 1914-8. Not only was much of the previously acquired knowledge put into practice, but this practical application in turn revealed or emphasized the gaps, defects, and errors in many current conceptions, and so led ultimately to the prosecution of new researches and the acquisition of much new knowledge. Surveyed from the most general standpoint, the war appears to have taught us little that was new regarding malaria and the other protozoal diseases already mentioned. Its chief protozoological contribution has been to our knowledge of those Protozoa which live in the human intestine, and more especially to the elucidation of the disease called amoebic dysentery. We may therefore say a few words on this subject at this point.

The Protozoa known as “amoebae” form a large and interesting group. Most of the species live independently in such places as ponds, ditches, or the soil; but some of them live in the bodies of other animals, and one of them—called *Entamoeba histolytica*—was already known before the war to live in the human bowel and “cause” amoebic dysentery. The parasite was discovered by Lösch in Russia as long ago as 1875. Its real relation to dysentery, however, was not made clear, though much debated, until just before the war, when the admirable researches of two American workers in the Philippine Islands—E. L. Walker and A. W. Sellards—were published. During the war their results have been confirmed and greatly extended, chiefly by the investigations of British workers. As a consequence, we now know as much about amoebic dysentery as we do about malaria or the diseases due to trypanosomes. There are several points here which are worthy of mention.

We now know that no less than five different species of amoebae may live in the intestine of man, though only one of these—the “dysentery amoeba” already mentioned—ever does him any harm. Moreover, we now know also that amoebic dysentery is a comparatively rare disease. There are many different kinds of dysentery, and the kind due to amoebae is far from being the commonest. Before the war amoebic dysentery was generally recognized as a disease more or less restricted to the tropics, though certain other kinds of dysentery occur all over the world. The curious fact brought into prominence by the war is that the dysentery amoeba itself is very common almost everywhere. This parasite, which can cause, by its presence in the bowel, a violent and sometimes fatal form of dysentery, usually does no such thing. Very many people, in all parts of the world, are infected with it, but very few ever suffer any appreciable harm from its presence. The parasite and the person who harbours it are usually suited to one another in such a way that they can live together comfortably, oblivious of the existence of one another. There are, for instance, in the British Isles at this moment many thousands of people who are

heavily infected with these disease-producing parasites, and yet enjoying perfect health.

Another curious feature of amoebic dysentery is the circumstance that it cannot be contracted from a person suffering from the disease. The people responsible for the spread of infection are those who harbour the parasite but themselves suffer no ill consequences from its presence. The explanation of these seemingly contradictory facts is really quite simple, now that we know the life-history of the amoeba and its relation to disease. It is a popular fallacy to suppose that any parasite is the sole "cause" of any disease. A disease is a joint result of many antecedent factors, and in the present case it would probably be nearer the truth to say that the person who harbours the amoeba, rather than the amoeba itself, is the "cause" of amoebic dysentery. For dysentery results only when the infected person happens to be abnormally sensitive to infection with the amoeba, and the condition is as harmful to the parasite as it is to the patient. Normally man and amoeba fit one another, and there is no trouble. Abnormally there is a misfit, and amoebic dysentery is the consequence. The disease is really an unimportant side-show in the life-history of the parasite, the result of its being planted in unsuitable soil.

The foregoing considerations will serve to show once more the value of protozoology in the study of human diseases. What hope could there ever be of eradicating a disease such as amoebic dysentery if we remained in ignorance of the life-history of the parasites connected with it? We might cure every case of the disease—we might conceivably prevent the death of every patient who contracted it; but even if we did, it is now clear that this would have no effect whatever upon the continuance and prevalence of the disease itself. Such procedure could not possibly stamp out amoebic dysentery, or even reduce by one the annual number of cases of this disorder. This is not to say that protozoology has yet enabled us to do either of these things; but it has enabled us to formulate the problem correctly, and has shown the uselessness of expending our energies in wrong directions. Greater results will follow when our knowledge is greater and more properly and consistently applied.

It has been supposed for so long that the parasites which produce protozoal diseases are peculiar to tropical or sub-tropical countries that the discovery of the dysentery amoeba in Britain may seem surprising. It is really not so surprising as the circumstance that nobody, until quite recently, had thought of looking for it here. And there are many equally remarkable parallels. To mention only those diseases and parasites which we have already noted, we can now say that malaria occurs indigenously in Britain—though this was hardly suspected until recently; and that parasites closely similar to those which cause nagana and Texas fever have now been discovered in the sheep and cattle of the United Kingdom. How far these observations are of practical importance the future will show, but already they clearly indicate that protozoology may be studied with profit at home no less than abroad.

Organisation and Training of Workers.—In conclusion, we shall now note very briefly what has already been done for the promotion of protozoology as a branch of science.

As a profession it still hardly exists. Most of those who have enlarged the science have been zoologists or medical men engaged in teaching other subjects and in practising their professions. Many great discoveries have been made by men who cannot be described as protozoologists. But the science has now become so vast, from the amassing of myriads of complicated details, that it can no longer be regarded as an occupation for anyone but a highly trained specialist. The amateur toying with his microscope, the ordinary zoologist or physician working in occasional vacations or leisure hours snatched from practice, can no longer expect to make any solid contributions to protozoology. In future all great advances in knowledge must come from those who are bred up as protozoologists—who not only have the necessary physical and mental gifts for this most difficult study, but who also are prepared to devote their lives and energies to it, and to it alone.

Modern science has already developed to such unwieldy proportions that it has ceased to be coherent and has burst asunder into separate segments. The day of the "scientist," with all science for his province, is gone for ever. If men of science are to escape the fate of the builders of the Tower of Babel, it can only be by conscious coöperation. Each worker must do his own special work, but must do it with due regard for his fellow-labourers in adjoining sections, and with the plan of the whole building constantly before his eyes. Protozoology must, accordingly, develop along its own lines and by the labour of protozoologists, but it must remain in touch with the rest of zoology and with medicine and with all other sciences whose collaboration is likely to be mutually beneficial. We can already observe the bad effects of non-collaboration in the modern school of protozoology which originated with Fritz Schaudinn in Berlin. Over-specialization has there led—after beginning on an admirable foundation of fact—to fantastic speculation and the promulgation of doctrines which are biologically unsound.

One of the good results of the World War was to encourage the collaboration of workers in different branches of science, and in Britain the bonds which previously existed between protozoology and medicine have been greatly strengthened. One of the most obvious conditions necessary for the continuance of this alliance is the growth of protozoology itself. Unless the protozoologists can build solidly, and not too slowly, they will lose their advantages. Unfortunately, no adequate provision has yet been made for the training of workers in protozoology. At present there are in Britain and elsewhere few first-rate professional protozoologists and few competent teachers, but a large number of day labourers and dabblers from other sciences. Protozoologists are still mainly recruited from other professions. The remedy for this state of affairs will be found only when protozoology is recognized as a separate science—an occupation for specialists and not for smatterers; and when encouragement is given to its development by the founding of professorships in the subject—or similar appointments—in the larger universities. These professorships must be primarily for research, and secondarily for teaching purposes. The professor must have ample time and funds for teaching himself, and for carrying out his own researches. If he is sufficiently gifted to do both these things, he will be able at the same time to teach his science to others who would follow in his footsteps. But the time has now gone when the junior demonstrator in zoology or the lecturer on general parasitology in the medical schools can expect to "take up" protozoology for a term or two and thereby profit science or himself. Unfortunately, too little had been done up to 1921 to create the necessary facilities.

A professorship in the subject, founded on the right lines, was indeed instituted in London University some years ago, but it had remained unoccupied up to 1921 since the death of its first holder in 1915. At Cambridge the Quick professorship of biology, founded later, at one time appeared likely to develop into a chair of protozoology, but these hopes were not fulfilled. An assistant professorship, chiefly devoted to protozoology, recently existed in the Imperial College of Science in London; but no further appointment was made to this post after it was vacated by its first occupant. The medical schools of Great Britain have, in some instances, lecturers in protozoology, but these are mostly medical men with other work to perform and no special knowledge of the science as a whole. The schools of tropical medicine in London and Liverpool have been more fortunate, and have been able to appoint to their staffs protozoologists who can devote their undivided attention to the subject. But here again it is chiefly the practical side of the science, as applied to medicine, that is being fostered. Rothamsted Experimental Station has a protozoologist to study the subject in its agricultural aspects, and several universities and other institutions of minor importance have members who have specialized in protozoology. Veterinary medicine in Great Britain has, however, still done little for research or instruction in protozoology.

In the British colonies and dependencies things are no better. A chair of protozoology has recently been created in India;

but as a general rule protozoological research and teaching are still being carried out under unfavourable conditions by hard-worked professors of other subjects. The valuable work already done by many of these men is surely a sufficient pledge of the profits that will accrue when more adequate provisions are made.

If we turn to the United States we find that Columbia University has a professor of protozoology and Johns Hopkins an assistant professor. There is also an American professor of protozoology in the Philippines. But with these exceptions, and a few of lesser importance, protozoology is advancing in America and elsewhere by the labours of zoologists and medical men whose appointments were not primarily established for the furtherance of the science.

RECENT LITERATURE.—The most trustworthy of recent books dealing with the Protozoa as a whole are those of E. A. Minchin, *An Introduction to the Study of the Protozoa* (1912), and F. Doflein, *Lehrbuch der Protozoenkunde* (4th ed., Jena, 1916). See also D. Bruce and others (1903-1919), *Reports of the Sleeping Sickness Commission*, i.-xvii. (Royal Society, London); C. Dobell (1911), "The Principles of Protistology" (*Arch. f. Protistenkunde*, vol. xxiii., p. 269); C. Dobell and others (1921), *A Report on the Occurrence of Intestinal Protozoa in the Inhabitants of Britain* (Medical Research Council, Special Report Series, No. 59, London); C. Dobell and F. W. O'Connor (1921), *The Intestinal Protozoa of Man* (London); S. P. James (1920), *Malaria at Home and Abroad* (London); H. S. Jennings (1906), *Behavior of the Lower Organisms* (New York); A. Laveran and F. Mesnil (1912), *Trypanosomes et Trypanosomiasis* (2 ed. Paris); E. L. Walker and A. W. Sellards (1913), "Experimental Entamoebic Dysentery," *Philippine Journ. Sci.* (B. Trop. PRYOR, ROGER ATKINSON (1828-1910), American jurist and politician (see 22.533*), died in New York City March 14 1910. In 1912 he published a volume of *Essays and Addresses*.

PRZEMYSL, SIEGES OF, 1914-5.—The Galician town of Przemyśl (see 22.534) was first fortified in 1854, when Austria mobilized against Russia. The completely exposed position of the N.E. frontier made it imperative to lay out fortifications. The Archduke Charles had already, in 1824, called attention to this weak point. In case of an invasion of East Galicia by the Russians, the first natural obstacle capable of bringing them to a halt would be the river beds of the lower San and the Dniester, and the obvious thing to do was to strengthen this line by constructing a series of fortifications. On the San it was originally intended to build out Jaroslau as a fortress, but the decision in 1854 fell on Przemyśl. In later years a row of smaller bridge-heads and *points d'appui* arose along the Dniester, which greatly increased its value as an obstacle. In the course of one year a fortified ring of no less than 65 forts had been erected round the town of Przemyśl. The year 1870 saw the building of a permanent ring of forts finished, but the works were not a match for a bombardment by modern siege guns, owing to the very niggardly expenditure sanctioned. Although after 1888, and in the last years before the World War, the modernization of the fortress from a technical standpoint was begun and some modern self-contained forts were constructed, it was in 1914 still in a very unsatisfactory condition. The short time available for equipment between the first days of mobilization and the first siege by the Russians was indeed spent in feverish activity, but only a very small part of the neglect of the past 20 years could now be made good. The works on the ring of forts, which was 48 km. in circumference, were more or less out of date. Only 12 of them could be considered "bombproof," while all the rest were only "shellproof," and even so only against 24-cm. bombs and 15-cm. shells of old-fashioned construction. The *points d'appui* for the infantry and the battery emplacements lying between the forts were almost without exception only splinterproof shelters, and some were mere field fortifications constructed of wood and earth. The infantry line running through these was protected by wire obstacles, generally only three rows deep. In front of the line of the ring of forts one enormous task had to be undertaken in preparing for the defence—the clearing of the foreground. No less than 18 villages and from 7 to 8 km. of forest were levelled to the ground. Numerous barracks, ammunition magazines, communications, bridges and other buildings, had still to be erected within the ring. The armament of the fortress was also

on a very low footing, consisting of about 1,000 guns in all, of which more than half were short-range weapons for ditch defence, and in *traditores*. These were 12- and 15-cm. cannon dating from 1861, 15-cm. mortars dating from the 'eighties, and 8-cm. cupola, disappearing cupola, and minimum port guns of old construction. About 450 of the guns were distant defence guns, being for the most part old 9-cm. field guns (M 75/96) with a range of only 6 km. Of modern guns the fortress at the beginning of the war had altogether only four 30.5-cm. mortars, with a range of 9.5 km., and 24 8-cm. field guns dating from 1905, effective up to 7.5 kilometres. The distant defence guns also included some 12-cm., 15-cm. and 18-cm. siege cannon, dating from 1880, 10 10-cm. and 15-cm. cupola howitzers made in 1899, 15-cm. mobile howitzers of the same year, and 24-cm. mortars made in 1898. As regards munitions the average provision was 500 rounds per gun, and not even that in the case of the modern mortars. For all the four 30.5-cm. mortars taken together there were 300 rounds in the fortress. Of machine-guns there were altogether 114, one-third of which were built into the forts, leaving two-thirds for mobile use.

For the purpose of provisioning the fortress an estimate of 85,000 men and 3,710 horses had been established. In peace time one month's supplies were stored in the fortress, with the understanding that an increase to three months' should be made during the arming period. The Austro-Hungarian Higher Command did its utmost at this time to increase the store of supplies, and, by making full use of the available railways and motor columns, succeeded in provisioning the fortress for four months and a-half. These precautions were all the more justified as, at the last moment, the garrison was augmented by the addition of the 23rd Honved Inf. Div., two field tramway sections and other minor formations, which brought up its strength to 130,000 men and 21,000 horses. At this strength the fortress was provisioned, not for four and a-half, but for three months.

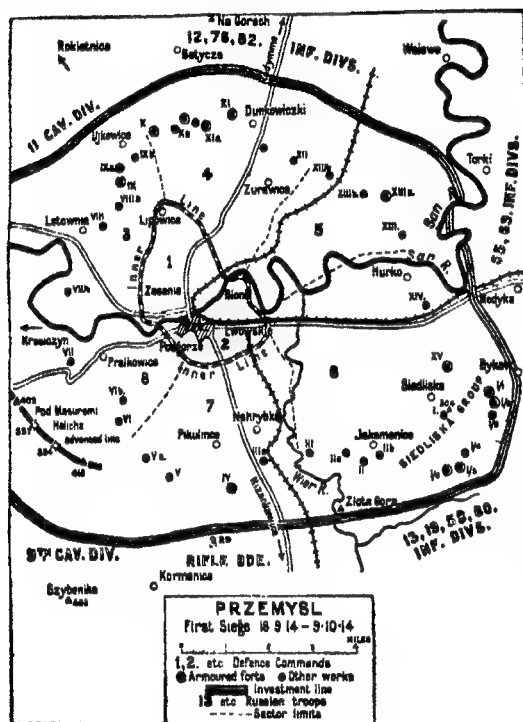

The actual garrison of the fortress at the beginning of mobilization consisted of the Austrian 111th and the Hungarian 97th Landsturm Inf. Bdes., one reserve squadron, one reserve battery, 40 companies of garrison artillery, 44 Landsturm artillery brigades, 7 companies of sappers, and the essential sanitary and labour detachments. When the Austro-Hungarian armies retreated behind the San, after the breaking-off of the battle of Lemberg-Nawa Ruska, there were added to the fortress command (under Field-Marshal-Lt. Kusmanek von Burgneustädten) the Austro-Hungarian 93rd and 108th Landsturm Inf. Bdes. and the 23rd Honved Inf. Division. Earlier additions had been: two Hungarian march regiments, of which, however, one was handed over to Jaroslau and Radymno, one Hungarian Landsturm hussar unit, and lastly a group consisting of four battalions formed out of various Landsturm formations, auxiliary police and others, cut off from the main body. All in all, the fortress establishment, when the last man of the mobile armies had left the zone, consisted of: 61½ infantry battalions (of which 40½ were Landsturm), 7 squadrons, 4 field-gun batteries, 43 fortress-artillery companies, 48 Landsturm artillery brigades, and 8 sapper companies; also sanitary corps, military and Landsturm labour detachments, fortress and tramway formations, balloon detachments, telegraph, telephone and radio formations, and so forth. The value of the troops shut up in the fortress may best be judged by the facts that two-thirds of them were Landsturm, including therefore older and less trained men, and that the formations which had been fighting on the open field were reduced to nearly half their strength. There had been, since the beginning of the World War, only two brigades to take duty in the fortress, and one of these even was sent temporarily to the IV. Army Command. The rest of the troops in the fortress were therefore not over-familiar with the duty of the fortress.

The Russian siege army, commanded by Gen. Radko Dimitriev, consisted originally of the whole of the III. Army, with the IX., X., XI. and XXI. Corps and parts of the IV. and VIII. Armies. When the Austro-Hungarian forces resumed the offensive in the beginning of Oct. 1914, the Grand Duke Nicholas withdrew three divisions of the III. Army from the circle of

PRZEMYSL, SIEGES OF

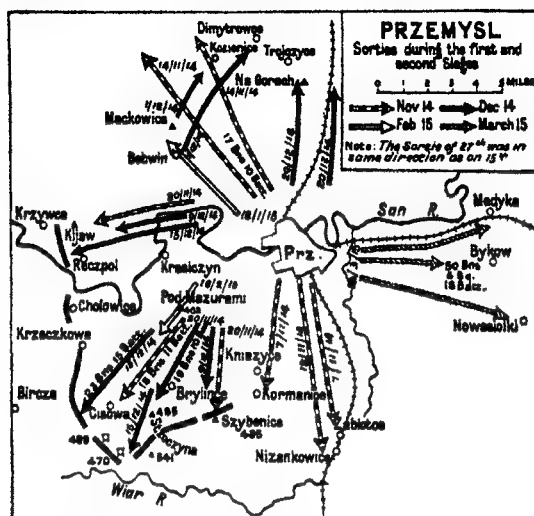

bombardment and sent them to the lower Vistula, with the object of enveloping the enemy. There were now nine and a-half infantry and two cavalry divisions left behind for the blockade of the fortress. Three of these divisions were posted on the N. front, half a division on the S., while the main force of six divisions encircled the E. and S.E. front, which was the point of attack actually fixed upon by Radko Dimitriev, and the two cavalry divisions were encamped on the W. and S.W. front. Counting the Russian infantry division at 16 battalions and the cavalry division at 24 squadrons, the Russians employed no fewer than 150 battalions and 48 squadrons, 800 guns of the field army and the heavy guns of the siege-artillery parks in the siege of Przemyśl.

The First Siege, Sept. 18-Oct. 9 1914.—On Sept. 18 1914, when the Austro-Hungarian armies had marched off westwards from the San and the area of the Przemyśl fortress, the fortress was left to itself, with orders—issued to Kusmanek on the 16th—to resist “to the uttermost.” The building of the ring of forts and the distribution of the fortress garrison in the defence zone had now been completed. Only one correction had to be made in the line of defence—on the S.W. front, where it lay too near to the town itself, thus exposing the town and the San bridges to the danger of a direct bombardment. Kusmanek therefore selected a position in the foreground, 2 to 3 km. in front of the ring of forts, running from Krasiczyn over the height of Pod Mazurami to that of Helicha, and had this rapidly fortified and occupied by four battalions. This measure obliged the Russians to fix their line of investment at a corresponding distance from the town at this point also.

The Grand Duke allowed only a very cautious pursuit of the retreating Austro-Hungarians by the Russian armies. The IV. and V. Armies advanced toward the N. of the fortress and across the San; the VIII. Army was ordered to push forward through the Chyrów and Sambor area, and S. of the fortress to the ridge of the Carpathians; the III. Army was to take up a position immediately in front of the E. front of the fortress. On Sept. 20 the first Russian detachments crossed the San at Walawa, to be followed at once by other troops coming from Radymno and Jaroslau, where the bridgeheads had been surrendered to the Russians. These troops surrounded the N. front of the fortress.

Portions of the III. and VIII. Armies now advanced towards the S. and S.W. fronts, while on the W. front two cavalry divisions by Sept. 24 completed the hemming-in of the fortress. By means of numerous very vigorous sorties and by violent artillery fire, Kusmanek succeeded in his task, which was to draw as many Russian forces on to himself as possible. He turned the Russian investiture into an exceedingly difficult undertaking.

The first great sortie was executed by Maj.-Gen. Weher, Commandant of the VI. defence zone, with five battalions and two batteries, on the Grodek road and S. of it, to force back the Russian line of investment between Medyka and Byków. Taken entirely by surprise, the Russians fell back from the first position, and two infantry divisions brought up to their support suffered heavy losses from the artillery fire which now began.

Kusmanek's next opportunity was when he learned that considerable forces were concentrated in the Nizankowice-Kurmanowice-Fredropol area, with the intention of passing along the S. side of the fortress to push forward towards the west. On Sept. 29 he sent Field-Marshal-Lt. von Tamásy with the 23rd Honved Inf. Div. to attack them by way of Halicha in the direction of the Saybenica height. Here the result was the forced deployment of considerable Russian forces against the 23rd Honved Inf. Div., and consequently the delaying of the Russian westward advance.

Minor sorties on other fronts were also successful, and everywhere a lively artillery battle was kept up in order to rivet the enemy's attention on the fortress. The Russians, for their part, maintained a violent bombardment of the forts in the ring. On Oct. 2 an interruption occurred in the Russian gunfire on the E. front. A *parlementaire* distinguished by a white flag brought a message from Radko Dimitriev demanding the surrender of the fortress. He was sent back as quickly as he had come bearing Kusmanek's written answer to Radko Dimitriev: “Herr Kommandant, I consider it beneath my dignity to give your insulting demand the reply that it deserves.” Thereupon the hail of steel on the forts began afresh.

Kusmanek's refusal had hit Radko Dimitriev hard. It was scarcely possible to fulfil the Tsar's wish and bring about the speedy fall of Przemyśl. A *coup de main* was impracticable, because the siege artillery material was still too far away and could not be fetched up quickly enough on account of the bottomless roads. In the first days of Oct., too, the Austro-Hungarian offensive was launched, and this might within a very short time bring Przemyśl the looked-for relief. Radko Dimitriev therefore found himself obliged to revert to a curtailed form of attack, and now tried to make up for the defectiveness of his artillery and technical preparations by reckless onslaughts. As the Austro-German general offensive had necessitated the removal of some of his N. front divisions to the mobile armies, he made up for

but as a general rule protozoological research and teaching are still being carried out under unfavourable conditions by hard-worked professors of other subjects. The valuable work already done by many of these men is surely a sufficient pledge of the profits that will accrue when more adequate provisions are made.

The rest of the troops in the fortress were therefore not over-familiar with the duty of the fortress.

The Russian siege army, commanded by Gen. Radko Dimitriev, consisted originally of the whole of the III. Army, with the IX., X., XI. and XXI. Corps and parts of the IV. and VIII. Armies. When the Austro-Hungarian forces resumed the offensive in the beginning of Oct. 1914, the Grand Duke Nicholas withdrew three divisions of the III. Army from the circle of

* These figures indicate the volume and page number of the previous article.

had broken off the battle of Przemyśl and the San in the night. Once more Kusmanek was confronted with the same tasks as in September. Shortly before the retreat of the field armies the fortress had been reinforced by the 85th Landwehr Bde. and a company of airmen. The strength of the garrison was approximately the same as at the beginning of the first investment. In order to extend the fortress's sphere of action, and to force the Russians to keep their line of investment at a greater distance from the actual ring of forts, at the same time obliging them to use more forces for the occupation of the longer line, Kusmanek had new foreground positions laid out. These formed a curve beginning at the Na Gorach height, and, passing 2-3 km. in front of the western ring of forts, came out S.E. of Krasieczyn at the old foreground position. From Helicha this position was extended to the S. of the fortress through Złota Góra up to the Siedliska group. This measure secured a double advantage: it placed another obstacle in the way of the attacker, who would have to surmount it before he could assault the ring of forts; and the works would suffer far less from the bombardment, as the siege artillery would be forced to remain farther away from the fortress. On the 9th the investment of the fortress was completed for the second time. The Grand Duke Nicholas had selected the Russian XI. Army under Gen. Selivanov for the siege. This army, consisting of about four infantry and one to two cavalry divisions, had barely half the forces used in the first siege under Radko Dimitriev. This circumstance, and the comparatively small activity shown by the Russians at the beginning of the second siege, pointed to the conclusion that Selivanov was less concerned with a rapid seizure of Przemyśl than with the idea of a regular siege, in which he would effect a saving of men on his own side while exploiting the scarcity of food supplies in the fortress, leaving the garrison to grow weak from starvation before he advanced to a serious attack. Kusmanek, on the other hand, displayed all the more activity. The months of Nov. and Dec. he employed in aggressive defence, and only desisted when the decimation of his forces by disease forced him to do so. In nine sorties he seized every possible opportunity of damaging the enemy, of preventing any withdrawals from his forces to the field armies; of destroying his supply trains and lines of communication, and finally of bringing into the fortress any food-stuffs—such as fruit and vegetables—which could be collected. In Dec., when the Austro-Hungarian armies took the offensive again, these sorties gained in importance, for each important action undertaken by the fortress with the object of containing Russian forces was necessarily a great disadvantage to the Russians defeated in the battle of Limanowa-Lapanów. Above all, in the case of a successful advance by the right wing of the III. Army, the possibility of co-operation between that wing and the sortie troops was not excluded.

On Nov. 7 and 12 further sorties were undertaken in the direction of Nizankowice and Kormanice. On the 14th, following on a report by the airmen of movements of Russian forces through Pruchnik to the W. and S.W., an assault was delivered on Rokietnica by 17 battalions and 10 batteries. For the same reason an equally powerful sortie was made from the S.W. front on the 20th, the main force moving on Cisowa, and the side columns towards Krzyweza and the Szybenica height.

In Dec. the Russians also became more active. Having let Nov. go by without doing more than prepare a more or less systematic siege, they now began their attacks and turned Dec. into a month of many battles. Quite at the beginning the 82nd Inf. Div. advanced against the N. front. Kusmanek delivered a vigorous counter-blow from the area of Mackowice against the enemy's right flank and repulsed the attack. On Dec. 9 this action was followed by yet another sortie by 19 battalions and 10 batteries from the S.W. front, with the object of preventing the departure of the Russian 81st Inf. Div.

In the middle of Dec., when the battle of Limanowa-Lapanów had reached its height, Kusmanek received an order from the Army Higher Command to deliver a fresh assault. In the hope of being able to join hands with Kr. 13's group, advancing on the right wing of the Russian army, Kusmanek prepared for a

great undertaking. With 23 battalions and 15 batteries, commanded by Field-Marshal-Lt. von Tamásy, he pushed forward on the 15th in the direction of Bircza and Krzywca. After four days of victorious fighting, the heights halfway between Cisowa and Bircza were captured, the enemy driven back along the whole of the S.W. front, and the road to Bircza laid open. But as Krautwald meanwhile had been forced back by the Russians, and as the hope of effecting a junction with him had become a forlorn hope on account of the great distance intervening, and as, further, a fresh violent attack had been launched against the northern foreground position, Na Gorach, Kusmanek found himself obliged to turn his attention to this latter, and to recall Tamásy on the 19th to the fortress.

Once more it was the Russian 82nd Inf. Div. which advanced on Na Gorach. Portions had already penetrated the advanced positions when Kusmanek's counter-attack set in on the 20th, and on the 21st threw them back to the line of investment.

At the end of Dec. yet another order from the Army Higher Command led to a fresh sortie. After the battle of Limanowa-Lapanów the Russians, taking advantage of their interior lines, had opened a counter-offensive against the troops of the III. and IV. Armies which had pushed forward into West Galicia. The proposal was for a sortie to be made in a south-westerly direction, falling in with the left flank of the Russian attack on the one hand, and on the other making a second attempt to effect a junction with the III. Army's right wing, which was pushing forward towards Lisko, Sanok and Rymanów. But with the suspension of the offensive on the 28th the sortie troops were brought back.

This sortie brought the offensive activity of the garrison to a close for the time being, in consideration of their ever-increasing losses through fighting and sickness. All forces were now to be reserved for the effort on a large scale to relieve the fortress, which was planned for the middle of February.

The month of Jan. saw the beginning of a period of great self-denial and sacrifice for the garrison, in consequence of the increasing scarcity of food. The commandant and his staff had in addition the difficult task of maintaining the striking power of the garrison with insufficient means, which involved exacting the maximum of service from each individual soldier in spite of his lack of nourishment. On Dec. 1 1914 Kusmanek, counting upon a delay in the relief operations, had ordered the first general reduction of rations for men and horses. At the end of the month the first horses were killed for the purpose of providing meat and saving fodder. Had the fortress been consuming its full rations it could not have held out beyond the end of Jan., but by the reduction of the ration and further slaughter of horses (up to 7,450), supplies were eked out until the end of March. The extension of the life of the fortress was in proportion to the establishment of horses it was necessary to keep up. For the projected break-through sortie and for the absolutely essential fortress duties a minimum establishment of 4,500 had to be allowed for. By means of further reducing the ration, resorting to incredible makeshifts, and sacrificing 3,500 more horses, the provisioning was made to last until March 24, but there was a rapid mounting-up of the sick list. By the beginning of March one-fifth of the fortress establishment had fallen. To the scarcity of food was added in the winter months that of clothing, footwear and all the other necessities of life. The garrison had been equipped, for the most part, with summer clothing, and even this had been badly damaged in the fighting. In respect of technical and artillery supplies also, the fortress gradually lost its power of resistance. The barrels of the guns had been gradually burnt out by the excessive demands made on them, and the range of the guns declined accordingly. The stores of ammunition were also rapidly coming to an end, despite the utmost economy.

While the striking power of the fortress was suffering sensibly from all the unspeakable privations imposed by hunger, cold and want, the besiegers were gradually becoming more active. At first the Russians confined themselves to increasing the air-men's activity. Almost every day their airmen circled round the fortress, with very little hindrance from its quite inadequate means of defence, dropping bombs on the forts and the town. In

the beginning of Feb. the systematic bombardment of the fortress set in. In the middle of the month the besiegers brought up the line of investment nearer to the N.W., W. and S.W. fronts. On the night of the 18th three regiments attacked the foreground position at Pod Mazurami, but were beaten back with heavy losses. It seemed to the Russians that the garrison's striking power was still too strong; and they let three weeks pass before equipping themselves for an important attack. On March 13 a powerful Russian force advanced against the N. foreground position Na Gorach-Batycze. Against so strong an attack, delivered by at least two regiments, the 33th Light Inf. Regt. could make no stand. As other powerful Russian forces were advancing against the N. front from Radymno, and as Kusmanek considered his own garrison too weak for a counter-blow and also wished to save his forces for the great final break-through, he gave up the foreground position and refrained from counter-attacking. At the same moment the Austro-Hungarian Higher Command had reached the conclusion that the II. Army's offensive would not be able to bring about the desired relief of the fortress, which was therefore inevitably doomed, since the food supplies would be exhausted by March 24.

A break-through from the fortress might conceivably save a portion of the garrison for the Austro-Hungarian army forces, and it had therefore to be attempted. In consideration of the state of supplies, March 19 was fixed as the latest time limit for its execution. Kusmanek had already made all the necessary preparations. He was free to choose the direction in which the sortie was to be made. His decision fell on the E., as it appeared to him impossible for his exhausted men to effect a junction with the II. Army through the mountainous area. On the E. the ground was practicable, and he might hope to have an opportunity there of destroying Russian railway lines and communications, and also possibly to have the good fortune to capture a Russian supply store. In case the break-through failed, he would then be able to take back provisions into the fortress and so prolong its life by a few days.

With two infantry divisions and three independent infantry brigades (50 battalions, 6 squadrons and 18 battalions) the break-through was begun on the morning of the 19th. After some opening success the troops, in a heroic seven-hour battle, fought their way up to the Medyka heights, coming to a stand here at 10 A.M. A flanking counter-attack by the Russian 58th Reserve Div., which had been brought up from the Carpathians, then forced them to return to the fortress, their losses being heavy on account of their exhaustion. The fate of the fortress and the garrison was now finally sealed. The Russians realized the aim of this last sortie, and they had captured on prisoners the order regarding it; they therefore knew that the fortress was almost at the end of its power of resistance. Kusmanek now awaited their attacks. All the sortie troops had returned to their old positions on the 19th. The same night the Russian masses made a violent assault on the E. front. Until the morning of the 22nd Selivanov exerted himself to the utmost to take the fortress by storm. An endless bombardment by the heaviest-calibre guns set in, and was followed by assaults on the N.W., N. and N.E. fronts, as well as on the E. front and the foreground position, Pod Mazurami. But the brave defenders held their ground and repulsed one attack after another. At last Kusmanek, armed with authority from the Army Higher Command, decided to destroy the fortress, since it was now quite impossible to save it. On March 22 between 5 and 6:30 A.M., just as renewed Russian attacks had begun, the works were blown up as far as possible; all guns, the small remaining store of ammunition and the technical arrangements were demolished, all arms broken, motors and other vehicles burnt, and the remaining horses shot. Kusmanek then sent a *parlementaire* to the Russian siege army. When the conditions for the surrender had been fixed the Russians entered the town to take over the administration.

Kusmanek betook himself at once with his staff to Selivanov's headquarters. The garrison,¹ which was allowed all military

honours and looked upon even by the enemy as a model of military bravery, remained about another week in Przemyśl, and was then removed in large detachments by way of Lemberg. On the 24th the Russian General Artamanov took command.

After four and a half months of heroic defence the fortress of Przemyśl had fallen, through hunger and sickness. To the brave garrison, and in the first place to the determined commandant, Gen. von Kusmanek, and to Gen. von Tamásy, leader of most of the sorties, the highest admiration was due, and the victorious enemy, whose own courage was proved by the enormous tribute of lives sacrificed before the forts and ramparts of the fortress, recognized this in full measure.

Recapture of the Fortress, May 30-June 3 1915.—Soon after the fall of the fortress of Przemyśl the Russians had taken in hand the reorganization of its works. Particularly after the visit of the Tsar, who inspected the destroyed works in the second half of April, the reconstruction was taken in hand with feverish haste. Numerous heavy guns, including French ones, were brought into the fortress, and a strong garrison was maintained. By the middle of May Böhm's and Puhalló's armies had advanced in a concentric attack on the positions S. of the fortress, as well as on the S., S.W. and W. fronts, while Mackensen's army pushed forward in the area N. of the fortress and over the San. While the Allied armies were thus advancing on Przemyśl the Russians were undecided whether to hold the fortress or not. By the middle of May they had begun the work of evacuation and the withdrawal of troops. But in the second half of the month the idea of holding the fortress gained ground, and the Grand Duke finally ordered it to be held "to the last extremity." When Mackensen's army began its offensive on May 24 on both sides of the Sklo in a south-easterly direction, the fortress became more and more closely surrounded to the N. also by the ring of investment. By the 30th the necessary heavy artillery had also been brought up, in spite of the delay caused by the ruined roads and bridges, and the bombardment of the S.W. and northern fronts immediately began. These were the two fronts against which the attack was to be directed. While the X. Corps of Puhalló's army stormed the S.W. front, the Bavarians of the XI. Army, in conjunction with one Prussian infantry regiment, one Guard battalion, and the dismounted troops of the 11th Honved Cav. Div., executed the main attack on the N. front.

Misled by the violence of the attack of the Austro-Hungarian infantry regiments (the 9th and 45th of the X. Corps), who, on the 30th, stormed the Pralkowce fort, on the S.W. front, Work VII., the Russians awaited the main attack there and brought their whole strength into play against the X. Corps. But although they were able to force the Austrians to evacuate the fort, they could not themselves reoccupy it. Meanwhile the Germans had done good work on the N. front. Their bombardment was mainly directed against the forts, X., Xa., XIa. and XI., lying between Ujkowice and Dunkowiczki, and for this guns of all calibres, including the 42-cm. mortars, were used. On the 31st, after heavy fighting, ending in a *mêlée*, Forts Xa. and XIa. were taken, as well as the adjacent infantry positions, and Fort XI. capitulated. On June 1 the Russians brought up strong reserves, but not in time to avert the fate of the fortress. On the morning of the 2nd Fort X. fell into the hands of the attacking forces after its obstinate resistance had been overcome by a liberal bombardment. By the evening Fort XII. had also been captured, and Forts IXa. and IXb. surrendered to Maj.-Gen. Berndt's cavalry. The break-through of the ring of forts had succeeded. North of Zurawica the Russians made one more stand; but this line had also been forced by the evening of the 2nd, and the Russians betook themselves to their last line of resistance immediately in front of the nucleus. But the attack did not get as far as this, for the Russians abandoned the fortress on the night of the 2nd, influenced probably by the successes attained by the XI. and II. Armies. Their rearwards took up new positions on the E. front of the fortress on the line Medyka-Siedliska.

At 3 A.M. the Bavarians of Lt.-Gen. Kneusel's division entered the fortress from the north. Maj.-Gen. Berndt followed from the N.W. with the Austro-Hungarian 4th Cav. Division. By 6

¹ In round figures 107,000 men, among whom were 28,000 invalids both fit and unfit for transport.

A.M. the Austro-Hungarian X. Corps had also come in. But the attacking forces did not remain long in the evacuated town. In a hurried pursuit they overran the Siedliska position and pushed forward to the E. of the town.

The fall of Przemyśl fortress, which had been subdued in barely four days, meant for the Russians the loss of the most powerful pivot of their San front. Not without reason had the Grand Duke—who had tried to gain a success over the IV. Army by a violent assault at Rudnik during the hard struggle for Przemyśl—ordered the fortress to be held "to the last extremity." By its fall the forces of the Austro-Hungarian III. Army and the German XI. Army were set free, and could go to the aid of the dangerously situated IV. Army. On the 4th the Russians abandoned the San front. Thus the recapture of Przemyśl, apart from the great moral impression it made, was decisive also in a strategical sense. (E. J.)

PSYCHICAL RESEARCH (or **SPIRITUALISM**) (see 22.544).—The matters referred to under the general name "Psychical Research" are distinguished from ordinary subjects of scientific interest by two characteristics. They appeal to the sense of wonder and the love of the marvellous and are concerned with "superstitions," that is, with beliefs which, after being ingrained in the human soul by an immemorial past, are now disavowed by science, but still affect human action. Secondly, they seem to involve abnormal extensions of human faculty, and are readily taken to indicate a survival of human personality after death, and a possibility of obtaining authentic communications from the departed. They consequently arouse strong emotional reactions, provoke strong dislikes and are peculiarly susceptible of vitiation by self-deception, bias and fraud. Hence they are usually treated in a partisan spirit on both sides, like matters of politics, and not with scientific impartiality, and the good faith as well as the competence of the witnesses have always to be tested and every allegation has to be verified. In all these respects the subjects of psychical research are intimately bound up with the religions; but it would be a mistake, nevertheless, to relegate them to the "supernatural," and hastily to declare them unfit for scientific investigation. Their investigation is difficult, but not impossible, provided that in a given society it is favoured or permitted. Of course, if it is proscribed as "sorcery" and made a capital offence, as was the case all the world over until recently, investigation will languish, and it may well be that the practice of burning psychics as "witches," persisted in for many centuries, has effectively eliminated most of the possessors of unusual faculties. However, to begin with, the term "supernatural" should be discarded. It merely assumes what is the cardinal point at issue, viz. that the realm of nature has been completely explored; and only omniscience could assert this. The allegations to be inquired into by psychical research, therefore, should be described, neutrally, as "supernormal."

Nevertheless, the peculiarities of the subjects of psychical research condition further differences which should be noted in any account of their history. They render the influence of public opinion far more important than it is in the ordinary subjects of scientific inquiry. It is true, doubtless, that everywhere the progress of any subject of human interest depends on two factors, on the quantity and quality of human intelligence devoted to its elucidation, and on the social atmosphere, i.e. the attitude towards it taken up by public opinion. Of these the former is ordinarily more conspicuous and important, for it directly affects the progress made. The latter acts indirectly, by affecting the amount and sort of the attention paid to a subject, and its effects do not all lie on the surface. But if there is in a society a real desire for more knowledge on a subject, research into it will be organized; inquiries will be set in motion, adequately equipped and endowed, and the conduct of such inquiries will become a career. If, on the other hand, there is little interest, nothing will be done; as also if knowledge is supposed to be absolute or adequate, or if its absence is held to be inevitable and is acquiesced in. If, lastly, the knowledge sought is feared or disapproved of for any reason, various measures will be taken for effectively repressing interest in it; nor must it be supposed that

such social taboos cease to operate merely because witch-burning has ceased to be a popular entertainment. In general, moreover, subjects which are inchoate and contentious are far more sensitive to changes in the social atmosphere than those which are recognized, established and endowed. For toward the latter the social attitude is fairly stable and changes only slowly, and they possess, moreover, a permanent organization, which provides for their cultivation (or is supposed to do so), and on which their progress mainly depends. In the case of the former, progress may depend chiefly on the social attitude, and indeed may even consist chiefly in a change of social attitude. It is unreasonable, for example, to expect progress in psychical research so long as the energies of researchers have to be devoted primarily to eluding the police or the officers of the Holy Inquisition.

The history of psychical research during the decade 1910-20 provides excellent illustrations of all these reflections. It is composed of a short pre-war period of obscure labour in the cold shade of social neglect, a short eclipse due to the complete immersion of all scientific workers in the pursuits and passions of the World War, accompanied by a grotesque ebullition of superstitions long supposed to have become extinct, and followed shortly afterwards by an astonishing revolution in social sentiment, which rendered psychical research popular and reputable as it had never been before, but is now slowly yielding and relapsing into the pre-war tone of feeling. Before the World War the great bulk of public opinion was either hostile to the subjects of psychical research, or at any rate indifferent to their scientific investigation. That, at least, seemed to be the obvious construction to be put upon the general indifference towards scientific psychical research, and was borne out by the results of a *questionnaire* intended to test the extent and depth of the desire to have knowledge of the most exciting of these subjects, viz. the individual's survival after death. The answers, as analyzed by the writer in the *Proceedings of the Society for Psychical Research* (pt. 40, 1904), seemed to indicate that such a desire was actively functional only in comparatively few minds at any one time, and that these were nearly always excited by the stimulus of a recent bereavement. This explanation seemed, moreover, to account sufficiently for the ordinary social attitude towards the subject. For it would follow that under normal circumstances the great majority, who were *not* animated by the bereavement-sentiment, would effectively repress the few who were, and would mould public opinion and social institutions accordingly—as had manifestly happened—both to scientific and to religious "orthodoxy." But it would also follow that if for any reason the bereavement-sentiment should become widespread, powerful and dominant, it might be predicted that there would ensue a great outburst of interest in psychical research, and a passionate demand for any method that held out to the bereaved human heart the immediate consolation of a direct communication with the departed.

Accordingly this is what happened in consequence of the World War. If we put aside, as mere "propaganda" for the benefit of the superstitious, the crop of bogus prophecies that accompanied the outbreak of war, and such successful appeals to primitive credulity as the legends of the "Russians from Archangel," and of the "Angels of Mons" (the latter, though published as *fiction*, was actually taken as *fact*), we find that at first the normal peace-sentiment persisted. It remained engrossed in mundane affairs and showed itself by a complete and exclusive absorption in the war. Nothing else seemed to matter, and scientific inquiries that did not minister to the war were simply dropped in an ecstasy of patriotic fervour. It seemed, therefore, the sheer waste of a guinea to continue to subscribe to an inquiry whether the human lives that were sacrificed so prodigally on the battle-fields were really dead and done with. No wonder the membership of the Society for Psychical Research in England went down from 1,205 in 1913 to 1,055 in 1916.

Meantime, beneath the surface of social convention, the bereavement-sentiment was growing to proportions unparalleled in civilized history. It was merely awaiting a signal to reveal itself. The signal was presently given, in a high academic

quarter, by the courageous act of a bereaved father, who did not shrink either from exposing himself to academic ridicule or from divulging the private evidence which he had obtained of his son's survival and declaring that it had satisfied him. That a distinguished physicist at the head of the university of Birmingham should openly endorse spiritism was a remarkable event; yet Sir

*Sir Oliver
Lodge's
"Ray-
mond."*

Oliver Lodge's *Raymond* (1916) was not in itself a remarkable book. Evidentially it did not show that Mrs. Leonard produced anything markedly more conclusive and better in quality than the evidence obtained long before through Mrs. Piper and other "psychics"; nor was there anything remarkable about the quantity of its evidential communications. Hardened sceptics should have had no difficulty in explaining away the "hits" it narrated, as they had dealt with its many predecessors. Nor did its version of the after-life differ markedly from the descriptions of the "summerland" that had been the staple of spiritist literature for the past 30 years, while its apparent crudities, e.g. of ghosts smoking "cigars" and drinking "whiskies-and-soda," were no less susceptible of a "symbolical" explanation.

But what turned out to be remarkably different was the reception of the book. It was found that patriotism paralyzed the voice of criticism. The scoffing reviewer, who had been accustomed to say that interest in psychical research was "morbid" and a sure passport to the lunatic asylum, or that the mystery of the grave was insoluble and that anyhow no sensible man had the slightest desire to solve it, was no longer regarded as the sort of person to express what the public wanted to hear about a book of that kind. So he was not allowed to touch it, or perhaps himself experienced a change of heart. Able editors perceived that, in war-time, consolations that appealed to millions of bereaved hearts must be treated tenderly, if only to keep the home front unbroken. So *Raymond* was reviewed respectfully and copiously, and enabled to break down the barrier of peace-time convention. A flood of lesser books followed, ascribed to the living or returning dead, and mostly composed of communications received by relatives of fallen soldiers, through automatic writing—not without an admixture of pious fraud. Unfortunately they were mostly written by people who paid little or no attention to the difficulty of getting evidential communications and of making their value apparent to their readers, and who considered the mere form of the communication as a sufficient authentication, being wholly ignorant of psychology and of the tricks they were, unconsciously, capable of playing on themselves. Nor did amateur automatism alone profit by this innovation. Professional "psychics" obtained an enormous vogue. The resignations from the Society for Psychical Research ceased, and accessions took their place. The membership went up from 1,055 in 1916 to 1,305 in 1919; and the new members were not only willing to pay the two-guinea subscription of a "member" instead of the guinea of the "associate," but insisted on a more active and enterprising policy, and came within measurable distance of "hustling" this eminently respectable society into an endorsement of spiritism.

Of course a change in the social attitude produced in this way cannot be permanent. The old influences persist, and will inevitably reassert themselves and produce a relapse into the former apathy, unless the exceptional opportunities are exploited, and the abnormal will to believe is fortified by positive achievements. In the long run, therefore, the status of psychical research will depend, not on the mere intensity of the desire to know and the amount of social approval it can secure, but on the amount of solid scientific work that will have been accomplished under the stimulus of the abnormal social conditions. It is necessary, therefore, to turn to the scientific side of psychical research, though the developments here will be found to have been relatively small and by no means commensurate with the volume of popular interest excited by the war.

Nevertheless a certain amount of scientific progress has been made, enuring both to the benefit and to the detriment of psychical research. It may be classified under the following heads: (a) Psychology, (b) Multiple Personality, (c) Telepathy,

(d) Trance, (e) Automatic Writing, (f) Physical Phenomena, (g) Downings, (h) Thinking Animals.

Psychology during the war made considerable progress because numbers of academic psychologists were compelled to practise, and to apply their theoretical conceptions to clinical problems, while numbers of medical men, finding themselves unable to cope with the profound disturbances of mental equilibrium, inaccurately, but conveniently, designated as "shell-shock," were compelled to reckon with the psychical side of medicine. Thus were large bodies of intelligent men forced not only to apply their theories to concrete cases, and to correct them by their working, but also to recognize the power of the disordered mind to simulate the most various lesions and diseases of the body. As might have been anticipated, the older systems of academic psychology, being compiled out of aesthetic preferences, metaphysical prejudices, methodological assumptions, introspective observations of conscious states, and highly artificial and limited laboratory experiments, did not stand the test of application to the battle-field at all well.

The "psychoanalytic" method, however, devised long before by Dr. Sigmund Freud of Vienna, for tapping the unconscious depths of the mind and bringing their contents to the surface was found to be capable both of explaining the symptoms and in many cases of suggesting a cure. Hence though the psychological theory on which Freud worked had seemed (and been) improbable, extreme and crude, and had (justly) encountered the strongest emotional repugnance, there was no gainsaying the practical validity of his method, and the reality and importance of the mind's unconscious structure. The mind had to be conceived, like the spectrum, as having invisible (unconscious) extensions, as truly characteristic, as susceptible of investigation, and in some respects as important, as its visible (conscious) regions. It had in consequence to be admitted that psychic contents could be "repressed" into this unconscious region without thereby losing their identity and reality, and could thence continue to produce effects in consciousness, even by those who refused to follow Freud in assigning none but an erotic motive to this repression. These psychological discoveries had a considerable bearing on several branches of psychical research. They seemed to throw a flood of light on the mechanism of multiple personality. A "repressed complex" could explain the growth of a "secondary self." They also modified the notion of "fraud."

Not only was it clear, as had indeed already long been recognized by investigators, that a secondary or trance-personality might perpetrate a fraud of which the primary or normal self might be innocent, incapable and unaware, but a personality of either kind might become unaware of the fraud it had committed by "repressing" its knowledge thereof. Thus the problem of the fraudulent medium was enormously complicated, and it could be suggested, as by Dr. Culpin (*Spiritualism and the New Psychology*, London, 1920), that even the most honest mediums were frauds, who had cleared their consciences by "repressing" the knowledge of their delinquencies. Furthermore, this same process might be used to explain many errors and gaps in the narratives of observers of supernormal occurrences. Having "repressed," as unwelcome, the real facts, they might honestly deny that they had ever possessed or divulged the knowledge they were bent on regarding as supernormal: it would thereupon appear to be so. Hence repression of the truth would have to be added as a third to mal-observation and forgetfulness, as a very subtle source of error in testimony to the occurrence of the supernormal, and would further complicate the problem of what the evidence really proved. On the other side it is fair to remember that whatever goes to show how little we really know as yet about the functions of the mind should act as an encouragement to psychical research, and renders more credible *pro tanto* claims to unsuspected powers.

In the field of multiple personality Dr. Morton Prince has extended and confirmed his brilliant researches, attending particularly to the proof of the reality of "coconscious" secondary selves (cf. his *Unconscious*, 1914). It will doubt-

less have gratified the readers of his *Dissociation of a Personality* (1906) to learn that "Miss Beauchamp" was afterwards happily and healthily married though her husband did not know what a heroine of psychological romance he had espoused. The most striking and substantial contribution to the subject is, however, contained in the

Multiple Personality.

admirably recorded and narrated story of the strange case of "Doris Fischer," for which science is indebted to the Rev. Dr. Walter F. Prince, who in consequence became interested in psychical research, and subsequently (1920) succeeded the late Prof. J. H. Hyslop as secretary of the American S.P.R. The record extends over three large volumes (1915, 1916, 1917) of the *Proceedings of the American S.P.R.*, contains almost 2,500 pages of print, and is fully worthy of such elaborate treatment. It narrates how, as a little girl of three, "Doris Fischer" was thrown down violently by her drunken father, and so sustained a psychic fracture, which "dissociated" her into "Margaret" and "Real Doris," the former being a personage very similar to "Sally" in the "Beauchamp" case. But for 10 years no one discovered the dissociation, and even her mother only thought Doris a little odd and forgetful, when as "Real Doris" she displayed ignorance of what "Margaret" had just said or done. At the age of 16 another painful scene, at her mother's death-bed, led to a further dissociation and the emergence of a new personality. "Sick Doris" was born mature, grave, hardworking and conscientious, but totally ignorant of everything that had happened before her birth. Again the dissociation escaped detection, because "Margaret," whose "mental age" never rose above 10, undertook to instruct her uneducated partner, and succeeded, at the cost of all-night sittings and violent quarrels. Between these two the "Real Doris" was for six years almost completely crowded out. How she was restored by the skill and tact of Dr. Prince, after he had taken charge of the girl and discovered her condition and how first "Sick Doris" and then "Margaret" were weakened by being put to sleep whenever they cropped up, and grew younger and younger under this treatment, and in the case of "Sick Doris" actually infantile, until they finally evaporated, may be read in Dr. Prince's fascinating record.

Theoretically the case (which was fully reviewed by the present writer in *Proceedings S.P.R.*, pt. 74: cf. also the article by Dr. T. W. Mitchell in pt. 79) is important also for two reasons. In the first place it brings out that the dissociations were plainly protective, and relieved the strain of an otherwise intolerable life. Secondly, they were attended by a considerable number of supernormal incidents which, though not unprecedented in other cases of dissociation (e.g. the "Watscka Wonder"), had not formerly been recorded properly. Indeed, if one can accept the record in vol. iii. of the sittings "Doris Fischer" had with Dr. Hyslop's medium "Mrs. Chenoweth," these incidents were the clue to the whole affair, and the dissociations were caused by, or complicated with, spirit-possession. But this interpretation is not apparently accepted by Dr. Prince, and is something of an excrescence on the main story.

Telepathy.—Little progress has been made in establishing telepathy as a process in nature. It remains a sort of half-way house for those who do not feel able to deny the supernormal altogether and yet shrink from the spiritist interpretation. It fulfils this function best if its nature and operation are left vague, so that anything and everything may be set down to telepathy of some sort. Hence believers in "telepathy" have not any strong motive for coming to close quarters with their theory, while the more intelligent spiritists dislike it as rendering any conclusive proof of spirit-identity practically impossible. The opponents of the supernormal first use it freely to disparage the evidences of spiritism, and thereupon frequently proceed, somewhat illogically, to cast doubts upon its own reality. Telepathy, however, has one great advantage, that of being susceptible of experiment. Unfortunately such experiments as are undertaken not only do not succeed in increasing our knowledge of its conditions, but hardly even confirm the earlier experiments on which the existence of telepathy is based. The most noteworthy of the experiments that have yielded positive results were those

undertaken by Miss Miles and Miss Ramsden, published in the *S.P.R. Proceedings*, pt. 69 (1914). On the principle that anything supernormal may be attributed to some sort of "telepathy," one might perhaps chronicle here the very anomalous *Adventure*, experienced by two well-known academic ladies of Oxford in the gardens of Versailles, but not published until six years after the event, in 1911 (cf. the review in *S.P.R. Proceedings*, pt. 64).

On the other hand, elaborate attempts made by two psychologists in America to verify the existence of telepathy have led to results which at first sight appear to be wholly negative. Dr. J. E. Coover, of Leland Stanford Junior University, was specially endowed as a psychical researcher by the brother of its founder, and in due course produced in 1917 a book of 640 pages. Among its rather miscellaneous contents (it contains *inter alia* a pleasing account of the outwitting of a fraudulent "trumpet-medium" by hidden machinery) he describes 100 series of 100 experiments with cards (court cards omitted) made by 100 pairs of Californian students, for the purpose of testing the existence of telepathy as a faculty widely diffused in some slight degree among human minds. The "agent" was instructed to draw a card and to determine by casting dice whether to look at it or not, and in the former case to try to impress his knowledge (without contact) on the percipient; while the latter had to answer in both cases, but for about half the time would thus be really guessing at random. The results, when tabulated and added up, yielded in the first series of 5,135 genuine "experiments" 153 complete successes (most probable number, 128), in the second series of 4,865 control experiments or "guesses" 141 complete successes (most probable number, 122).

There was therefore a slight excess of successes, but Dr. Coover rightly argues that it was too small to be significant of anything beyond chance. He claims therefore to have disposed of the idea that telepathy may exist in minimal intensity in all minds, and evidently thinks that this disposed of the whole case. This, however, would seem to be going too far, on his own showing. For his figures do not dispose of the possibility that telepathy may exist in a faint degree in some minds. Indeed they rather suggest this possibility. For if we examine them with a view to testing this hypothesis, we may select, as *possibly slightly telepathic*, the series in which the "percipients" got 3 or more complete successes in their "experiments." There were 14 of these, in which 54 complete successes were scored in 711 experiments. The most probable number being 18, the excess is now large enough to be significant of something beyond "chance." But not, apparently, of telepathy, so much as of a sort of "lucidity" or "clairvoyance." For if we treat the (supposedly fortuitous) series of "guesses" similarly, we get still more remarkable results. The series with 3 or more complete successes once more turns out to be 14, and yields 49 complete successes out of 600 experiments (most probable number, 17). But curiously enough 5 of the 14 best "guesses" are identical with 5 of the 14 best "experiments." As the most probable number for such a coincidence is only 2, it can hardly be fortuitous. Moreover, if we add together the "experiments" and "guesses" of these 5 series, we get 41 complete successes out of 500 experiments, as against a most probable number of 12. Again something beyond "chance" is indicated. As, however, this something operates about equally well whether the percipient is trying to determine a card which was actually being thought or is only guessing, it can not be set down to conscious telepathy. This again accords with the other evidence that goes to show that telepathy, if it exists, is not greatly dependent on the conscious efforts of the mind; or otherwise, that if minds communicate telepathically, it is by way of the subliminal. For the rest, of course, the moral is that further experiments should have been conducted with the 5 successful pairs, in order to determine whether they would continue to produce a surplus of successes; but unfortunately this idea did not occur to Dr. Coover.

Dr. L. T. Troland also experimented in telepathy, with very elaborate apparatus, in the Psychological Laboratories of Harvard University (1917), in order to utilize an endowment given in memory of Richard Hodgson (cf. Review in *S.P.R. Proceedings*,

pt. 80). He, too, got negative results, and did not go on long enough. In fact, he failed so completely that he failed even to prove that telepathy did not exist, or that at any rate he and his colleague were completely devoid of telepathic ability. Only 605 experiments were made, and only 284 complete successes were obtained. Now this is very sensibly below the most probable number (302); but, as Dr. Troland observes, an abnormal deficiency is quite as significant of something other than chance as an abnormal excess. It may mean the presence of some factor that *inhibits* success, and if this can be established, it is just as supernormal as one that *produces* success. However, Dr. Troland does not hold that in his experiments the deficiency is sufficiently great. He has not observed how it arose. His total figures were arrived at by lumping together two sets of experiments. In one of these the stimulus shown to the "agent," to which the "percipient" was to react by pushing an instrument either to the right or to the left, was exposed for 30 seconds; in the other, for 15 seconds. Now in the former series there was no deficiency of right reactions; 120 successes out of 240 experiments are slightly above the probable number, 124. The whole of the deficiency was incurred in the 15-second series, which yielded only 155 successes out of 354 experiments, instead of a most probable 177. As the only difference between the two series was in the duration of the exposure, the idea easily suggests itself that the 15-second exposure was too short to enable the percipient to react rightly. And not only that; it seems to have positively inhibited the right reaction, presumably by inducing an "anxiety-neurosis." In other words, if the "agent," or more probably the "percipient," got "flustered" by the shortness of the exposure, his very knowledge of the right reaction would lead him to make the wrong one. Thus a marked deficiency in correct responses over a long series might imply as much supernormal knowledge, and yield as good evidence of telepathy, as a marked excess; much as it is implied in the "negative hallucination" of a hypnotic subject that he both sees and does not see, the object of the hallucination, and indeed that he *must* see it (subconsciously) in order to avoid it. Again, however, the series of experiments was not long enough to make the appeal to the calculus of probabilities decisive. For the present, therefore, it is best to conclude that the reality of telepathy is not yet either proved or disproved: the evidence is just about enough to keep it alive as a hypothesis.

Trance.—The phenomena of trance continue to be studied, and although Mrs. Piper, the most famous "medium" of this type, was pensioned by the S.P.R. and retired so long ago as 1910, she has no lack of successors. Indeed, the great majority of the customers of "psychics" frequent trance-mediums. Their manifestations continue to be much the same; entranced psychics become obsessed by one or other of their regular "controls"—usually grotesque personages that cannot be identified, and may fairly be suspected of being creations, at least to a large extent, of the medium's subliminal imagination. There are poured forth (in the "good" sittings one hears about) masses of details about the sitters and their concerns, often hesitant, inconclusive, vague, sometimes wrong, often non-significant, but sometimes so startlingly apposite as to shake all but the sturdiest scepticism. The evidence presented in Sir Oliver Lodge's *Raymond* was obtained in this way; Miss Radclyffe-Hall and Lady Troubridge have recorded similar evidential sittings with Sir Oliver's chief medium, Mrs. Leonard, in S.P.R. *Proceedings*, pt. 78. Mrs. Sidgwick produced a final and monumental review of the Piper case in S.P.R. *Proceedings*, pt. 71 (1915).

As regards the theoretic interpretation of these trance-communications, the tendency, even among those most inclined to believe that they convey authentic messages from the departed, is to complicate the process of communication. It is recognized more and more that there have to be reckoned with, not only the medium, with his natural limitations of faculty and training, but the medium's "subliminal" or subconscious, the medium's "controls," who are supposed to transmit the messages from the communicator proper, and possibly the effects of abnormal conditions, not only in the medium (trance-personality)

but also in the "control" and "communicator," owing to the effort to communicate. It is evident that these complications may account for many errors and obstructions; but they detract *pro tanto* from the authenticity of the actual communications.

Automatic Writing.—Automatic writing continues to flourish and to furnish psychical researchers with large masses of raw material. But its quality is not equal to its quantity, and its interest is for the most part psychological rather than evidential. Nevertheless a few cases of automatism laying claim to scientific importance may be noted. Undismayed by the failure of Mrs. Verrall to get, through automatic writing, at the contents of a sealed letter left, before his death, by Frederic Myers with Sir Oliver Lodge (*cf.* S.P.R. *Journal*, Jan. 1905), many of the leaders of the S.P.R. continued to work at cross-correspondences, and the results of their labours bulk large in the *Proceedings* of the society 1911-0. They discovered some curious cases among the writings of their automatists, the most remarkable perhaps being that entitled *The Ear of Dionysius* (1917), which was worked out by Mr. Gerald Balfour, and held to indicate the *post-mortem* agency of Prof. Verrall. But unfortunately the value of the coincidences on which the method relies is not capable of exact determination, and the whole method of proving *spirit-identity* by cross-correspondences is too literary and recondite to be appreciated without an intellectual effort, and so fails to impress the ordinary man. The automatic writing of a Dublin lady, Mrs. Travers Smith, excited some interest, both on account of the enormous speeds attained in its method of production (a planchette travelling over an alphabet under glass), and because of the claim that communications had been received from Sir Hugh Lane, before it was known that the *Lusitania* had been sunk, and that he had been one of the victims of this outrage. The case is narrated in *Voices from the Void* (1919).

Great interest was excited when Mr. Bligh Bond, in his *Gate of Remembrance* (Oxford, 1918), announced that he had been guided in his excavation of Glastonbury Abbey by the automatic writings of a friend who produced copious communications, largely in very debased Latin, from a number of the monks who had inhabited the Abbey from the 11th to the 16th century, and had revealed the correct location and dimensions of the Edgar Chapel, though all the extant antiquarian evidence had made these statements seem quite improbable. Mr. Bligh Bond also had the courage to print in the first edition of his book similar predictions about the Loretto Chapel, of which the remains had not then been found: when, after the war, excavation was resumed, these also were found to be correct substantially—*i.e.* allowing for the facts that the original script was in some points capable of more than one interpretation and that the excavators did not always hit upon the right one. Cases of practically valuable information received in a supernormal manner are extremely rare, and Mr. Bligh Bond's is one of the best of them.

Physical Phenomena.—To pass from automatic writing to physical phenomena is to pass from the least to the most contentious of the subjects that concern the psychical researcher, from a region where the facts are admitted and the interpretation alone is in dispute, to one where fraud has to be guarded against at every step and where *all* the facts are suspected by some to be due to it. Not that fraud is excluded in the former case: automatic writing can be simulated (like anything else) and with a little luck and ingenuity organized deception can be effectively practised with great success, as is amusingly shown in E. H. Jones's *The Road to Endor* (1920), describing how two British officers beguiled the tedium of their captivity and fooled both their comrades and the Turkish officials in charge of their prison camp. In fact, fraud is so easy that nothing depends on it; it is recognized by all competent inquirers that the whole value of automatic writing depends not on the mode of production but on the evidential character of the contents. In dealing with physical phenomena, on the other hand, the elimination or discounting of fraud is the primary consideration; the more so that fraud is certainly abundant, and that the conditions seem designed to facilitate it. This should be recognized by both sides, and should be no reason for refusing absolutely to investi-

gate cases in which *prima facie* the evidence is good, and fraud is absent or, apparently, impossible. As for the conditions, it may conceivably be that just as photographs must be taken in the light and developed in the dark, so the curious growths to be described presently can only be developed in more or less complete darkness. But the inadequacy of the lighting, even in cases where red light is allowed sufficient to distinguish the hands and faces of the sitters, is a valid reason for demanding that the deeds done in the darkness of the séance-room shall be mechanically controlled by adequate substitutes for the sitters' senses of sight and touch, which the darkness puts out of action or renders untrustworthy. To secure this control, it would probably be necessary to construct a special laboratory in which extensive machinery (incapable of forgetting or being hallucinated) would record all the physical changes going on during the sitting. It reveals a curious lack of seriousness in the human attitude towards psychical research that no such laboratory had yet been provided anywhere.

In spite of these drawbacks, however, physical phenomena will not down. There have been plenty of frauds, and plenty of exposures, including that of an Italian medium of international fame, Eusapia Palladino, who began the decade well with a favourable Report by Mr. Everard Feilding and Mr. Baggally on a series of sittings she had given them in Naples (S.P.R. *Proceedings*, pt. 62, 1911). These investigators, though they reported many movements of objects they could not account for, nevertheless emphasized that Eusapia needed continuous watching because she always cheated when she was given the chance. The chance was given her when she went to America in 1909, and the result was a very handsome and complete exposure, which eclipsed her reputation, even though many of her patrons continued to hold that nothing new had been proved against or about her mediumship, and that it was not wholly fraudulent. Still she died obscure (1918) and fashion took to other mediums.

At present a somewhat different type of physical phenomena is in vogue, in which puzzling movements occurring within the radius of the medium's arm or foot are no longer the staple of the performance, and which it is more difficult to set down to fraud, because the evidence is largely recorded in flashlight photographs, which seem on the face of it to involve the supernormal. In particular two or three cases of "materializations" seem to be deserving of further study. The first of these is connected with a French lady known as "Eva C.," whose mediumistic career goes back to 1906 and the "Villa Carmen" sittings at Algiers, which ended in the customary charges, and denials, of fraud. Some years later she turned up in Paris, living in the house of Mme. Alexandre Bisson, and her materialization phenomena speedily attracted attention. Early in 1914 the chief German psychical researcher, a medical man, Dr. von Schrenck-Notzing, published a lavishly illustrated book, *Materialisations-Phänomene*, on the materializations of Eva and the similar performances of a Polish girl, Stanisława P.; owing to the war it was not translated into English until 1920. It describes the elaborate precautions taken against fraud and to secure the genuineness of the "materializations"; but the extraordinary flashlight photographs of the plastic substance out of which they were built up are even more convincing than the physiological reports on its character. It is shown exuding from various parts of the medium's body, chiefly the mouth (whether or not the head and the hands were enclosed in muslin bags), hanging about the body in festoons, and forming itself into fingers, hands and faces, which are often incomplete and usually flat and picture-like. This of course gives a measure of support to the only explanation which the sceptics have so far been able to excogitate, viz. that the pictures are first swallowed by the medium and then "regurgitated." This theory, however, hardly explains how they manage to reappear so unruined, or how the "plasma" is got through the muslin bag when the medium's head is sewn up, and back again. Nor does the medical and microscopic examination of small samples of the plasma which Dr. von Schrenck-Notzing was allowed to take confirm a stomacic origin: its character appears to be epithelial. The reports of Mme. Bisson and Dr. von Schrenck-

Notzing were subsequently confirmed by a French medical man, Dr. Gustave Geley, in a lecture given to the Psychological Institute at the Collège de France in Jan. 1918, on "Supernormal Physiology and the Phenomena of Ideoplasty," and in the summer of 1920 "Eva C." was very searchingly examined by a committee of the S.P.R. in a series of sittings held in London: phenomena were not as copious as in Paris, nor on so large a scale; but their general character was confirmed, and no trace of fraud was detected (*cf.* S.P.R. *Proceedings*, pt. 81).

The "materializations" of "Eva C." seemed at first to receive independent support from the mediumship of Miss Kathleen Goligher of Belfast. This medium, and the family circle in which she sat, were exhaustively studied by Dr. W. J. Crawford, a lecturer in mechanical engineering in the local university, who described his conclusions in a series of books; *The Reality of Psychic Phenomena* appeared in 1916, *Experiments in Psychical Science* in 1919, while the third, *The Psychic Structures at the Goligher Circle*, delayed by the author's sudden death, appeared in Feb. 1921. They formed a graduated series, growing more and more sensational in their results, and in the end actually represented as visible facts what had originally been suggested as hypothetical inferences. In his first book Dr. Crawford, while candidly admitting that he believed the directing intelligences concerned to be departed human spirits, set himself to study the mechanics of the phenomena observed, raps, levitations of the table, and other movements of objects, after establishing their supernormal character. For this purpose he used phonographs, manometers, spring balances and a variety of weighing machines, in a red light "nearly always" sufficient to show plainly the hands of the sitters, and proceeded to determine *exactly* the amount and incidence of the forces employed in producing the movements. As a result of his experiments, he came to the conclusion that the mechanical effects observed could only be explained by postulating hypothetical structures, with a definite shape, connecting the bodies moved with the body of the medium at her ankles. These structures, which he called "psychic cantilevers" and "psychic rods," though invisible and intangible, had a size, shape and position which could be mapped by observing at what points the phenomena could be stopped by interposing between the medium and the objects moved.

In his second book Dr. Crawford extended these results, and showed that ordinarily the weight the bodies levitated was added to that of the medium (as if she held them), while when this psychic substance was weighed in a weighing pan at a distance from the medium, her weight would simultaneously be reduced; he claimed to have observed a temporary loss in this way of as much as 54 lb., nearly half her normal weight. He also stated that he obtained impressions on clay of the ends of such a "cantilever column." Finally these structures became visible, and his last book is adorned with flashlight photographs appearing to verify the correctness of his deductions about their origin and application. Moreover, in appearance they curiously resembled the "plasma" issuing from "Eva C." By ingeniously applying moist dyestuffs to various points in the stockings and underclothing of the medium, Crawford claimed to have determined the course taken by this "plasma" in issuing from, and returning into, the body of the medium, declaring also that he had felt the collapse and recuperation of her muscles which accompanied these processes. As his narrative stood, the Goligher case appeared to provide the most impressive evidence ever obtained for the reality of "materializations." Dr. Crawford's premature death in 1920 made it temporarily difficult to pursue independent inquiry into the matter; but at the end of 1921 further investigation by Dr. Fournier D'Albe proved that the manifestations were fraudulent.

Observations of so-called "telekinetic" phenomena, i.e. movements of small objects such as celluloid or pith balls, match-boxes, teaspoons, balances, etc., without contact, in the presence of a Polish lady, Stanisława Tomczyk (now Mrs. Everard Feilding), who had been "dissociated" in consequence of experiences during the Warsaw riots of 1906, were reported by Prof. I. Ochrowski of Warsaw in the *Annales des Sciences*

Psychiques (1900-12), and confirmed by Dr. von Schrenck-Notzing in 1913-4. Some of the photographs appeared to give a clew to the mechanics of these phenomena by showing very fine threads connecting the hands of the medium and passing beneath the object levitated. It is argued however, partly on the strength of the negative results of investigating the medium before and after the phenomena, partly on the ground of differences in the appearance of these threads and of cotton, silk and hair (illustrated), that the threads were of a psychic and supernormal character, and in fact plastic emanations similar to those of "Eva C." In the summer of 1914 the medium came to London to be examined by the S.P.R., but the outbreak of war prevented the continuation of the investigation.

Another branch of physical phenomena is represented by what is called "spirit-photography." In this, as in the (now extinct) method of "slate-writing," everything depends on the prevention of fraudulent substitutions in the plates (or slates). If this is neglected, the production of "spirit-photographs" becomes easy enough. One of the earliest practitioners of this art, William Keeler, has recently suffered annihilating exposure of his "Lee-Bocock" frauds at the hands of Dr. W. F. Prince (Am. S.P.R. *Proceedings*, vol. xiii. 2, March 1920), after having had his case stated in *Proceedings*, vol. viii. (1913), of the same society. Other cases of "spirit-photography" may be said to be still under investigation, and, though none had in 1921 been proved genuine, their detection is usually a highly technical matter. Dr. Prince has also convincingly shown by a critical study of the evidence that an old "poltergeist" case, "the Great Amherst Mystery" (1879), was in all probability due to the (unconscious) fraud of the medium, who had been "dissociated" by a shocking event in her personal history, which she had, apparently, "repressed" (Am. S.P.R. *Proceedings*, vol. xiii. 1, 1910).

"Dowsing," as a method of finding water in dry places, continues to be used with considerable success, and it is certainly impressive to find that certain firms of well-sinkers regularly employ dowsers, and are so confident about their skill that they are willing to make contracts on "no find, no pay" terms. It is said, however, that they then (not unreasonably) protect themselves by charging higher rates. The subject was somewhat actively debated in Germany shortly before the World War, because the German governor of South-West Africa had a cousin who was a water-finder, and employed him with great success (cf. *Des Landrat von Uslars Arbeiten mit der Wünschelrute in Südwest Afrika*, Stuttgart, 1912). A pamphlet by A. J. Ellis, issued by the U.S. Geological Survey (*The Divining Rod*, Washington, 1917), though it dismisses the matter dogmatically as a mere superstition, has a useful bibliography.

Thinking Animals.—Before the World War Germany was also the chief home of a vigorous dispute about "thinking animals," which must be noticed in this connexion, not only because allegations of supernormal faculty were made, but because the logical problems involved, the difficulties in ascertaining the facts and in guarding against deception, and the partisanship of the disputants, were identical. For though at first the issue appeared to be simply a question of zoological fact, to be decided experimentally by biological and psychological experts, it soon appeared that not only was there the usual divergence between conservatives and progressives, but that the experts were divided by the conflict between the tendencies to emphasize the unity of life and to affirm the supremacy of the human mind; moreover, when, as was soon the case, a considerable amount of *odium theologicum* was imported into the discussion, a similar division was observable among theologians. The result was a complete replica of a controversy in psychical research. The trouble began so long ago as 1904, when Herr von Osten produced a horse, his "Clever Hans," which he had taught to do simple sums by tapping with his hoofs. He had proceeded on the logically false assumption that mathematical thought is peculiarly arduous, and on the biologically false assumption that to discover unsuspected extensions of animal intelligence would be particularly cogent in directions remote from the natural interests of the beast. However, "Hans" indisputably tapped

out the right responses in the presence of his master, and even (though rarely) in his absence, and the scientific scandal became so great that an inquiry had to be made (by order of the Ministry of Education); as a result the explanation was adopted, with the approval of the Berlin psychologist, Prof. Stumpf, that the observant animal reacted to slight, unconscious indications given by the experimenter. Thus there was neither thought nor fraud, but only visual hyperaesthesia (cf. Pfungst, *Clever Hans*, English translation, New York, 1911).

Officially this report was supposed to settle the matter. But an Elberfeld gentleman named Krall was not satisfied. He bought "Clever Hans" after von Osten's death, and examined his visual acuity, finding it to be 2½ times that of a man. He also trained up a whole stud of equine mathematicians, that became famous as "the Elberfeld horses." Among them one turned out to be a genius, "Muhamed," while another, "Berto," was blind, and so incapable of visual hyperaesthesia. Elberfeld became a place of pilgrimage; a multitude of books, pamphlets and articles appeared (cf. Krall, *Denkende Tiere*, Leipzig, 1912); a review was founded for the recording of the prodigies of animal thought (*Tiersehe*, 1913). Presently, at Mannheim, an invalid lady took to exhibiting a thinking dog, "Rolf," who, though not so mathematically minded, appeared to be gifted with a rare sense both of philosophy and humour. True, the animal refused to "work" unless held by a chain, and this procedure naturally fostered suspicions that the natural brilliance of his mind might have been improved by a little judicious wire-pulling; but there arose plenty of reputable observers to testify that the chain was kept slack, and even some to declare that "Rolf" had been known to answer correctly in the absence of his owner and had furnished answers not known to any human mind: the opposition, therefore, could only attack the competence of the observers, and sometimes succeeded in showing that they had been laxer than they had imagined. Yet, despite the indignant protests of those who claimed to have vestiges of common sense or knowledge *a priori* of where the limits of the possible were laid down, the open-minded (like Darwin), not afraid of "fool" experiments, went to see, and were duly puzzled: even eminent psychologists, like Prof. Claparède of Geneva, reported favourably, more or less. A poet, Maeterlinck, came away from the horses with the conviction that the phenomena were supernormal; and was satisfied that horses, dogs and cats were by nature "psychics," while elephants, monkeys and asses were not and, unlike the former, could not tap the cosmic reservoir of potential knowledge. The said "reservoir" was hypothetical, but seemed to be needed to provide for the correctness of answers not known to any human mind, and so transcending "telepathy" (which had also been suggested) (cf. *The Unknown Guest*, Eng. trans., 1914, p. 267).

Clearly, this question of "thinking animals" exhibits the tantalizing perversity of other problems in psychical research. The truth about it is not a problem in pure science, and is not susceptible of settlement by its methods. For these demand that the good faith of the observers can be presupposed and that undistorted observation of the facts is possible, both conditions often far less completely fulfilled, even in the established sciences, than is usually assumed. In the unreclaimed borderland between superstition and science neither condition can be satisfied; every "fact" may prove to be real only as a hallucination is real, or to be distorted into a monstrous *mirage* by prejudice and bias, while the will to believe (and equally the will to disbelieve) is so free to select, to emphasize, to interpret, that it can create practically any "fact" it chooses. In short, truth in this region is unmistakably emotional; men's attitude towards it essentially resembles their attitude in religion or in politics; the abstraction from human feeling (or rather from every feeling but the desire for knowledge), which is postulated in the ideal of pure reason, is simply impracticable here. So long as every "fact" adduced on either side has to be treated as suspect, and every step is contentious, scientific progress, if it is possible at all, cannot be otherwise than slow. There is only one way for believers in the supernormal to shortcircuit this procedure: if they can apply

their beliefs to the ordinary course of reality and show that they develop so much practical value that they must be reckoned with, they cannot in practice be treated as false. If, for example, secrets were regularly discovered, and information transmitted, by "telepathy," if fortune-tellers frequently told their clients how to make fortunes, and business "clairvoyants" were employed by financial houses, this pragmatic proof would be irresistible, and would suffice to convince the world. Actually, however, the pragmatic test rather tells against belief in the supernormal: for the supernormal knowledge believed in is not taken to be trustworthy normally; nor do believers in it act on it, thus betraying the fact, which they may not realize themselves, that they do not take their beliefs quite seriously. In this respect they are like very many other people. For, as Prof. Carverth Read (*The Origin of Man*, ch. viii., London, 1920) has shown, even among the most benighted savages believers in "magic" have always to behave sensibly, for all the extravagance of their beliefs. They pray, but they also keep their powder dry, and thus their action reveals which of their beliefs are only half-beliefs or make-believe.

In ultimate analysis the question becomes one of the place, function and significance of beliefs which are not quite matter-of-fact about what are not quite matters of fact. To appreciate these, we have to discard the illusion, traditionally fostered by logic, that there is no alternative to firm belief but whole-hearted disbelief. Actually the gradations and fluctuations of beliefs are infinite, and in many departments of life such unstable beliefs are normal and dominant. They can easily coexist with others, abstractly inconsistent with them, in a mind unwilling to abandon either, or perhaps unaware that it is entertaining them. Thus even Herbert Spencer showed that he had some belief in ghosts by his comical indignation when his hostess told him she hoped that so stalwart a disbeliever would not mind sleeping in the haunted room of a country house (*Autobiography*, i., p. 480). The only way of redeeming from this region of incomplete beliefs that are below proof a subject of general human interest—and no others ever fall into it—is to make it part of the ordinary routine of life, which every one accepts in practice (whatever the theoretic reason he may give to himself and others), simply because no one can ignore it and live. But if ever the objects of psychical research should be effectively subjected to such a transfer, this would clearly mean a spiritual revolution of the most far-reaching kind.

LITERATURE.—This is still largely contained in periodicals. In England those of the Society for Psychical Research must be mentioned in the first place. Both the *Proceedings* and the *Journal* maintain a high scientific and literary level, and contribute, record or review all the important developments of the subject. The addresses which are delivered by presidents of the society on coming into office form an interesting record of the attitude taken up towards the subject by a number of eminent thinkers (e.g. Henri Bergson, 1913; Gilbert Murray, 1916; L. P. Jacks, 1917; Lord Rayleigh, 1919; W. McDougall, 1920). But the society's publications do not notice all the tittle-tattle of the movement, for which it is necessary to consult the weekly *Light* and the monthly *Occult Review*. The former is the official organ of British spiritualism, and the latter is not sufficiently critical of the material it publishes, which, though entertaining enough, appears to be often (almost avowed) fiction. In July 1920 *The Psychic Research Quarterly* began to appear, which promises to be a high-class periodical, and in its Oct. number published the first photographs of Miss Goligher's "materializations." In America the *Proceedings* and *Journal* of the American S.P.R. have the same standards as the English society. But they were long edited by the late Prof. J. H. Hyslop (d. 1920), who soon became a convinced (though critical) spiritist, and reflect his work and his views in a very voluminous and somewhat one-sided way. They are now edited by his successor, Dr. W. F. Prince, the brilliant investigator of the Doris Fischer case, and the acute critic of sundry cases of fraud. In France the *Annales des Sciences Psychiques* have published some good material and continue to give a good idea of the movement in the Latin countries. The *Bulletin* of the Institut Général Psychologique used not infrequently to contain articles on psychical research, but now that an *Institut Métapsychique* has been founded in Paris, with an ambitious programme, it is probable that in future these will appear in its *Bulletin* (no. 1, Oct. 1920). In Germany *Psychische Studien* continue. In Switzerland the *Archives de Psychologie* used to publish valuable studies bearing on psychical research, but it was edited by the late Prof. Theodore Flournoy (d. 1920), the author of the famous study on the automatism of

"Hélène Schmidt," *Des Indes à la planète Mars* (1900), *Esprits et Médiums* (1911), and of the very remarkable study of a modern mystic "Cécile Vê" (in no. 57, 1915).

As regards books, many have been referred to above. The outstanding importance of Sir Oliver Lodge's *Raymond* and of W. J. Crawford's works on the Goligher case has been already explained under "Trance" and "Physical Phenomena." William James's "Final Impressions of a Psychical Researcher" was reprinted from the *American Magazine* in *Memories and Studies* (1911) and should be consulted for the conclusions left in the great psychologist's mind by his prolonged interest in psychical research. As books of a general character taking a favourable view of the phenomena, there may be mentioned Sir W. Barrett's *On the Threshold of the Unseen* (1917); J. A. Hill's *Spiritualism, its History, Phenomena and Doctrine* (London, 1918); J. H. Hyslop's *Psychical Research and Survival* (1913), *Life after Death* (1919), *Contact with the Other World* (1919); H. Carrington's *Problems of Psychical Research* (London, 1914), *Modern Psychical Phenomena* (1919), *Psychical Phenomena and the War* (1919). Among hostile accounts the best are I. L. Tuckett's *The Evidence for the Supernatural* (1912); E. Clodd's *The Question, If a Man Die shall he Live Again?* (London, 1917) and J. McCabe's *Is Spiritualism based on Fraud? and Spiritualism: a Popular History* (both London, 1920). Prof. M. Dessoir's *Vom Jenseits der Seele* (1917, 4th ed. 1920) is also unfavourable in the main, though appreciative of the attitude and work of the S.P.R., and interesting as coming from an academic psychologist who has not disdained to investigate the phenomena alleged. Dr. A. von Schrenck-Notzing's works are important (*Materialisations-phenomene*, Munich, 1914, 2nd ed. announced for 1921, Eng. translation by Dr. Fournier d'Albe, London, 1920; *Der Kampf um die Materialisations-Phenomene*, 1914; *Physikalische Phenomene des Mediumismus*, 1920). Dr. G. Geley's *De l'Inconscient au Conscient* (Paris, 1919) is an attempt to form a theory of the supernormal physiology of "Eva C." A translation by S. de Brath came out in 1920 (London). Lastly A. J. Philpott's *Quest for Dean Bridgman Conner* (London, 1915) may be instanced as an instructive investigation of an automatic romance (communicated through Mrs. Piper), which, though plausible and partially correct, turned out to be essentially false, and to illustrate how untrustworthy information obtained through supernormal channels at present is. As medical works dealing with psychotherapy and dissociations of personality, those of Dr. Boris Sidis, who made his mark by narrating the strange case of the Rev. Mr. Hanna (cf. Sidis and Goudhart, *Multiple Personality*, New York, 1905), *The Foundations of Normal and Abnormal Psychology* (London, 1914), *Symptomatology, Psychognosis and Diagnosis of Psychopathic Diseases* (Boston, 1914) and *The Causation and Treatment of Psychopathic Diseases* (Boston, 1916), may be mentioned; also W. H. R. Rivers' *Instinct and the Unconscious* (London, 1920) and W. Brown's *Psychology and Psychotherapy* (London, 1920).

(F. C. S. S.)

PSYCHOTHERAPY.—The modern branch of medicine to which has been given the name of "psychotherapy" may be regarded as covering all attempts made to mitigate or remove such symptoms as may be attributed to the operations of an unhealthy mind. These symptoms may be mental, for instance confusion of mind, or delusions, or obsessions, and may not be associated with any bodily symptoms or only with such as are trifling. On the other hand the symptoms may be bodily, for instance paralysis, or some form of loss of sensation, or indigestion, and may not be associated with any but trifling mental symptoms. The treatment of symptoms due to mental ill-health by physical agents such as rest, exercise, change of climate, baths, electricity or drugs is not psychotherapy.

Psychotherapy has been practised in all ages, sometimes upon those patently suffering from mental or moral disorders, but perhaps even more often upon those whose symptoms in fact depended upon mental or moral weakness or disorder but in whom the affection appeared, from the superficial character of the medical knowledge of the moment, to be due to organic disease of the body. In such cases psychotherapy has enjoyed considerable success, whether practised in connexion with religion and philosophy or with superstition and charlatanism (see FAITH HEALING, 10.135). Under circumstances such as these there has always been, and indeed still is, a formidable admixture of the miraculous, and it is not intended here to examine systems like that of Christian Science or the miracles of Lourdes. The term "psychotherapy" is of comparatively recent origin and has received wide acceptance in that it usefully stands for treatment based upon scientific psychology, normal and morbid. Three methods of psychotherapy will here be considered, from the purely medical point of view: those of Moral Suasion, Suggestion and Psycho-analysis.

Moral Suasion is historically the oldest method, and was advanced to a high level of excellence by the Stoic Philosophers. Illness, whether mental or physical, involves, to an extent depending upon the circumstances of the case and the character of the patient, pain and discomfort, disability with the fear of its consequences upon economic and social position and the fear of death. It is principally in the relief of discomfort and pain that persuasion has its success. Many patients are seriously alarmed at any abnormal feeling in any of their organs, are apt to call such feelings painful and to colour their descriptions with such adjectives as "awful" and "terrible." Others will ascribe symptoms of a commonplace character to serious disease of some important organ,—for example, when flatulence is mistaken for heart disease or turbid urine or pain in the back is regarded as indicative of kidney disease. Merely to induce such patients to be more precise in language and then in simple terms to offer some proximate explanation of their symptoms will often, without the association of any remedial agent, place their ideas in better proportion and mitigate or abolish their pains. Therapeutics have, very naturally, up till quite recent times been dominated by the endeavour to treat the symptom of which the patient complains rather than to attack the disease which is producing the symptom. For the most part treatment has been either by frankly miraculous methods or by those which have been in part empirical and in part miraculous, that is, by those in which some wonderful and unknown factor has seemed to coöperate with the supposed remedy. It has more recently become increasingly apparent that remedial agents not uncommonly owe their seeming success firstly to the fact that most disorders pass away whether treated or not, and secondly to the fact that the mental attitude of the patient can in itself assist at his cure and that this attitude may in many persons be modified for good or ill by the physician or other attendants of the sick man. Galen long since pointed out that "when the imagination of a sick man has been struck by the idea of a remedy, which of itself is without efficacy, it becomes endowed with beneficent power." The method of persuasion seeks to use this recuperative power which lies in the patient's mental field and to set it to work either without or with the assistance of physical agents. It seeks by reasonable explanation to impress upon the patient that his symptoms are transient and that his malady is curable, that it is important for him to aid in his own cure by taking a balanced view of the ills which afflict him and to face them with hope and courage. There is not, as in treatment by suggestion, an endeavour to impose an authoritative assertion to be blindly accepted as a matter of faith, but an endeavour to secure the penetration of an idea by the power of reason, to discuss the situation with the patient and to obtain his acceptance of the case as put forward by the physician. The fear of the disabling effect of illness may also be dealt with by the physician, who may point out, where he is so justified, that on recovery the disability will pass away or that if any be left it will be of an entirely trifling character. In serious disablement and in cases of which the end is likely to be death, it becomes the duty of the philosopher and the priest to fortify the courage and resignation of the patient. Not infrequently, however, the physician, willing or not, has himself to assume their functions and to adapt his exhortations to the needs of men of various creeds and levels of culture.

That persuasion on these lines is of value as a therapeutic agent there can be but little doubt, but its chief disadvantage lies in its limited scope, in that its appeal is to highly developed and organized faculties, just those faculties with which the neuropathic are not for the most part particularly gifted and which are the first to be weakened in disease. In practice, persuasion is apt to degenerate into partial explanations authoritatively enunciated, in which the physician has to make the best he can of the ignorance of the patient and of his own necessarily meagre scientific acquisitions, and in which pure ratiocination plays a small part. In short, persuasion merges into suggestion.

Suggestion, as a formal method of therapeutics, is but of recent origin (see 26.48). In large measure it has been, from the

earliest times, ancillary to miraculous, magical and professional modes of healing. Under other names it has often been the only curative agent and has been used uncombined with physical agents or ritual performances, but for the most part it has been practised in combination with these. Professional or scientific medicine, though seeing no way of escape, has often sought and still seeks to have as little to do as possible with so indeterminate and varying a mode of cure. It struggles after more exact and precise results, in the fond hope that at some distant date each disorder, psychic or somatic, shall either be prevented from occurring at all or if it occurs shall be met forthwith by some one rapidly acting and efficacious medicament.

The first great impetus to the use of suggestion as a formal method of therapeutics came from Mesmer during the latter part of the eighteenth century, and for well nigh a century suggestion, employed as such, was associated with hypnotism (see 14.201). The artificial induction, but not by drugs, of a state in some ways resembling sleep was first called by this name rather before the middle of the nineteenth century, and it was found that the hypnotized person was, in a great majority of cases, in a condition in which suggestions made to him were acted upon with astonishing accuracy either at once or at some subsequent time as determined by the hypnotizer, in short that his suggestibility or capacity for receiving and acting upon suggestion had been much increased. The word "suggestion" used in association with mental therapy has lost some of its precision. Few are agreed as to its meaning: no one can do more than speculate as to the mode of action implied by it. It is common to hear detractors of some cure, whether it be miraculous, or of the character of those relied on by Christian Science, or emanating directly from orthodox medicine, explain it as being "merely" due to suggestion. What is really meant by such an explanation is not always apparent, and it is desirable to restrict the meaning of the term "suggestion" as applied to therapeutics to the process in which it is sought authoritatively to instil an idea into the patient's mind with a view to the relief of some morbid process. From the catalogues of cases set forth by some practitioners it would appear that almost any affection is capable of amelioration or cure by suggestion. A more modest and a more generally held estimate would limit the cases amenable to this treatment to those of functional disorder and of organic disease in which super-added functional symptoms are a prominent feature. The difference between persuasion and suggestion, as indicated above, is that in the former an appeal is made, at least in theory, to the highest levels of the patient's mind, whereas in suggestion (and particularly in this the case when it is combined with hypnosis) directions are delivered to levels of which the patient is only partially conscious, or which he is not aware of as being concerned in the production of his symptoms, or which he does not hold to be capable of activation in their amelioration, or of which, indeed, he is wholly unconscious. In the endeavour to make use of such levels it is plain that it may be necessary to endeavour to inhibit the operations of those that are higher, since these are occupied largely and sometimes almost wholly by the miseries of the patient.

Suggestion suffers from the essential vice of the older therapy in that it is directed rather to the treatment of the symptom than to the disorder of which the symptom is but part. Movement may, for example, be restored to a paralysed limb, but the mental processes of which the movement is the outcome may nevertheless remain unhealthy. A coördinated purposive action is not wholly explained in terms of the movement of a limb, but involves preliminary sensual, perceptual, rational and volitional activities, one or several or all of which may be affected. Criticism has largely been directed against the method of suggestion in that it would seem to convert the patient into an automatic machine which responds to activation without knowing what it does or why it does it: there is obedience without reflection or judgment. Whether this be always so or not, the physician in any case is in ignorance as to which part of the whole psychological system he is operating upon; indeed he is ignorant as to which part of it is in a morbid state. Hysteria is held by many

psychologists to lie in mental dissociation, that is that the various mental processes do not coöperate harmoniously and that some are active while others are dormant. Suggestion in the hypnotic state seems artificially to procure this very state of dissociation, and in fact is widely held to induce a mental state analogous to, if not identical with, that of hysteria. To avoid so unhappy a result of a therapeutic measure as the establishment of a morbid state, endeavours have been made to practise suggestion when the patient is not under hypnosis, that is, when he is awake. It is nevertheless usual to direct the patient to allow his mind to adopt an attitude of passive receptivity, and when, if he can, he has done this to make suggestions to him. Only so far as the critical faculties are dormant are such suggestions likely to be efficacious, and if the critical faculties are dormant the method is open to such objection as may be made to hypnotism. This mode of suggestion is probably but little removed from the method of persuasion, the physician hoping that his case may be accepted under the guise of suggestion with a minimum of adverse criticism.

The term "auto-suggestion" has been used to denote a process in which the patient himself attempts to exercise a salutary influence upon his malady by concentrating his thought upon the idea of his cure or by, as it were, commanding his symptoms to disappear. The operation may be assisted by the withdrawal of the patient to a quiet place, by his placing himself in an attitude of repose and by his endeavour to empty his mind of all ideas save the one which is curative. Given sufficient intensity of purpose a man may by such treatment of himself rise superior to the ills that afflict him, think or act in spite of them, and, indeed, in certain cases annihilate them. It is not, however, given to many to reach success on these lines. Afflicted man seeks two things, one to know what really is the matter with him and the second to obtain succour from forces external to himself; he ardently desires a diagnosis and a healer. The desire for correct diagnosis is necessarily shared by him who aspires to be a scientific physician, prompts the constant search for the cause of symptoms and inspires the hope that, a cause being discovered, treatment will be more radical and effectual. Such ideas have led to the inquiries which of recent years have been instituted into the development of the human mind, both from the racial and from the individual aspects, and have resulted in new methods of mental analysis.

Psychological analysis (or "psycho-analysis") has been practised by the method of introspection for centuries. It involves the examination of his mind by the individual himself and the attempt to differentiate between such mental operations as those of feeling, knowing, reasoning, wishing and willing. Such inquiries eventuated in difference of opinion and ceaseless controversy as to the spheres of these faculties, as they were called; nor was the introspective method, owing to the difficulty of getting it efficiently practised by patients, of much value in morbid psychology. The newer methods of analytical psychology as applied to morbid mental manifestations, or to such bodily symptoms as might be supposed to be due to disordered mental processes, have addressed themselves to the discovery of a presumed basic causative idea, its association with other ideas, and its genesis.

The earliest signs of mind in the individual have the character of reflexes, that is, that upon the reception of a certain stimulus by the organism a particular series of movements ensues. Some of these pass by the name of instincts, are of a complicated character, and appear to occur without previous experience and without education or direction from without. Very early, however, in the history of the child the play of instinct is controlled, repressed or supplanted by positive injunctions from others, by the inculcation of habits, by lines of thought and conduct suggested to him by his observations of those about him, by his desire to imitate their doings and to repeat their sayings, and by his personal experience. The purely natural development of the child is interfered with in order that he may be fitted for life in a civilized society. During this process certain actions initially pleasurable come to be regarded as unconventional, or repre-

hensible, or shameful, or immodest, or all of these together, and so gradually rules of thought and conduct come into being. Almost all, and perhaps all, thoughts and actions are associated with some emotional tone, that is, with feelings of pleasure or displeasure or pain. Such feelings are of varying intensity, being in some cases so weak that they can scarcely be discerned and in others so powerful as to occupy and command the entire personality. During the education of the child a separation may be brought about between an action and the associated emotional tone or affect, as it is termed. If a child has learnt to regard a pleasurable act as blameworthy and in fact acts no longer in this particular way, the affect which was associated with the act may become partially or wholly detached from it and may perhaps be replaced by its opposite. It is one of the hypotheses of psycho-analysis that a dissociated affect of this character may produce symptoms at once or in later life, either because the affect has not been passed on to some other important or more legitimate object of activity and remains as a quantum of unused psychic energy, or because it has become attached to a substitute for its original partner of unworthy or ridiculous character. The gradual passing on of affects from lower levels of activity to those that are higher has been called sublimation, and their progress from the satisfaction of very lowly bodily wants to the highest ethical and aesthetic acquirements of the mind has been elaborately examined. The failure in attachment of an affect to any sort of substitute for its original partner may result in those indefinite emotional states, sometimes of a distinctly morbid character, in which the individual may be happy or miserable or excited or apathetic for no reason which is obvious to himself or to anyone else; while the attachment of affects to somewhat trifling and comparatively valueless objects is seen in the inordinate interest taken by some in domestic pets, bric-a-brac, pastimes, or fantastic and inane social entertainments. Sometimes, however, the affect remains unconverted and still attached to the original act, so that a conflict arises between the primitive and personal desires on the one hand and desires of later acquisition weighted with civilized, ethical, legal and religious authority, on the other. Many such conflicts are plainly carried on in full consciousness, and are examples of the lust of the flesh against the spirit and of the spirit against the flesh and of the contrariness of the one to the other, but others are by no means so obvious, and their existence may only betray itself by trifling, though odd, deviations from ordinary conduct, by unexplained prejudices and habits, or by symptoms of functional nervous disorder or by the yet more pronounced symptoms of insanity. The conflicts which lie in the field of consciousness may largely be dealt with, in so far as they come under the notice of the physician, in that field. The mere disclosure to another of the existence of a conflict may suffice to produce a therapeutic effect, and this may be further enhanced by the discussion of the subject and its illumination by another mind, but there are conflicts in which the opposing elements and their origin and genesis are not apparent or recognized or indeed discoverable without much labour. Such conflicts are said to lie in the field of the unconscious and to be due to the persistence in that field of repressions made at that time of life when the instinctive desires of the individual, tutored by early environment and education, have undergone a process of restraint. By a wide, and as it seems to some, unnatural extension of the term "sexual" the interest of the infant in its excretory functions and its relations with its parents is ascribed to the sexual instinct, and is that which, owing to existing social conventions, is most subject to repression. It is held that the relations of the child to his mother have an element of sexuality hitherto not determined. Hence the frequent occurrence of such terms as the "Oedipus Complex" and "incest" as descriptive of certain infantile affects. It is further held that the earliest interest of a child in itself is of a sexual character, that it is "auto-erotic." Progress is made from this stage to another in which the child's sexual admiration for himself is termed "narcissism"; then to one in which the interest is extended to other members of his own sex, and finally to one in which sexuality

becomes centred upon the normal object, that is upon the opposite sex. This development may be arrested at any point, and the arrest may later in life be displayed in various sexual perversions. If a person in whom such an arrest has occurred, say, at the stage of homosexuality, is living in a civilized society, difficult internal conflicts are likely in later life to ensue between the strength of his desires and his fear of outraging both social convention and legal enactment; or, owing to the fixation of his affect upon an object, not the normal end object of the sexual instinct, he may find himself impotent in his relations with one of the opposite sex. The efforts of psycho-analysis are directed towards the discovery of repression, arrest of development and the conflicts which are thus generated. If these can be brought to light there is hope that further development may occur, that unattached or badly attached affects may find appropriate and fitting objects, and that conflicts may be resolved by the co-ordinating action of the conscious.

Analysts are not, however, in complete agreement as to whether sexuality is the sole or essential cause of functional nervous symptoms. Some find in the desire of the individual to express his influence upon others, or his "will to power," an active determining cause of the internal conflict which arises when he finds himself in opposition to social conventions and to such activities of those about him as tend to impede his progress. Others again seek to find conflicts not so much in the past development of the individual as in the difficulties which arise when he endeavours to attain such ideal ends as he has proposed to himself. But whatever the value attached to the elements of causation of morbid states there is general agreement that it is not only the conscious field with its obvious conflicts which has to be explored but that the unconscious field should also be examined in as much detail as is possible.

The form of the content of the unconscious and of the conscious mind appears to be determined by analogous processes. Perceptions are apparently not invariably noted by the conscious. It is not an uncommon experience to discover perceptions which must have been made at a certain time and place which only well up into consciousness at some later date, while the details of a perception which were not clear or even considered at all at the time they were received, may be placed in their true position by analysis. In certain morbid states, for instance, delirium and mania, memories of events and even of languages which have been forgotten for many years, may be recovered. Such memories lie in depths of mind to which the term "unconscious" alone seems applicable. Constructive ideation and ratiocination appear also to proceed in the unconscious mind. Problems which have been propounded and set aside for a while receive, as it were suddenly and unexpectedly, a solution; indeed such solutions are recorded as having been reached during sleep. Similarly the execution of works of art, pictorial, musical or literary, is, especially in the case of genius, often effected without immediately preceding conscious mental effort, while the ideas of preachers, orators, wits and ordinary conversationalists often seem voiced automatically. Indeed the obtrusion of conscious effort not uncommonly mars rather than enhances the value of artistic expression. Conventionally the term "sub-conscious" has become restricted to those states of mind which, though not at the focus of conscious thought, can be brought to that focus at the will of the individual, but the differentiation between such states and those which are brought to consciousness only at exceptional times or by analytic methods seems to be of a very indeterminate nature. A much more particular meaning is assigned to the unconscious by some who make of it a rather sharply defined collection of primitive and instinctive infantile affects. Whatever may be the view adopted on this point, there is but little division of opinion as to the view that the affects which impel conduct, whether primitive or elaborated and sublimated, lie to a great extent in the unconscious, and the search for and examination of these affects when brought into consciousness constitute the great merit of knowledge of self. Not only does the unconscious seem to contain the powers already alluded to, but it has been sought to establish that there

is in it a something which has been termed the "censor" which seeks to prevent the emergence of unacceptable affects from the unconscious into the sub-conscious and thence into the conscious. To this "censor" is also attributed powers of transmutation of ideas and symbolization which render the crude and unpalatable operations of the unconscious less unacceptable to the conscious. The examination of dreams by the analytic method is held to have demonstrated the existence of such operations. The ideas of a given dream are one by one examined, with a view to the discovery of their associations, that is of their immediate relation with other ideas, and it is found that the manifest content of the dream is but a condensation of a much wider range of ideas and only indirectly and allegorically expressive of them. The dream is found to be the expression of an affect whose existence may perhaps not hitherto have been recognized and whose passage into the conscious has been prevented. On these points also there is not a complete consensus of opinion, and by some the analysis of dreams is held to disclose not only or so much the expression of the most primitive affects but also the ends which the individual in fact desires but of which he is but unconfessedly and dimly, if at all, aware. Indeed the interpretation of dreams seems not infrequently to depend not so much upon a thoroughgoing analysis as upon the psychological views and imagination of the interpreter.

Another method of exploration is that by free association. The patient is placed in a comfortable position and is directed to close his eyes and then to say whatever idea comes into his head, no matter how absurd or rude or otherwise offensive it may be. Ordinary volitional precautionary control being in this way relaxed, vent is given to the repressed content or at least various groupings of ideas are disclosed. Analogous results are obtained when, owing to intoxication or disease, patients reveal trains of thought remote from those to which in healthy states they give utterance, the very existence of which has been unknown to them and which when known is repulsive.

A third method of analysis is that by the "time-association" test. In this again the patient places himself in a comfortable position and relaxes his attention to what is going on or to any particular line of thought so far as is possible. He is directed to listen to certain words pronounced by the analyst, and on hearing one forthwith to say the word which first arises in his mind. The time between the signal word and the reply is noted. Normally the length of time is two to three seconds, and if it is prolonged or if after some 45 seconds no reply has been given the reaction is considered to be worthy of further examination and to indicate the existence of a group of ideas associated with a definite and perhaps marked emotional tone, that is, with a "complex," as such a group has come to be technically called. But the time element is in fact not the only one of importance in this test, since the character itself of the reply word is put to valuation. Test words may elicit replies of a rhyming character, or altogether commonplace, but on the other hand they may be so inconsequential and unexpected that a surmise at once arises that they imply the existence of a complex.

Such then are the methods adopted in analysis, and it must be plain that if carried out in detail they must necessarily occupy a considerable amount of time. Unhappily in practice analysis is apt, owing to the limitation of available time, to be slipshod, while deductions are hastily drawn from hastily gathered data; this is by so much the greater a misfortune in that the outstanding merit of analysis lies in its claim to be something of an exact method of examination and thus to supply in psychotherapy a way of discovering, and so of treating, the basis of the symptoms complained of. Though an analysis may not be thorough or the results of a thorough analysis may be incorrect, yet some amelioration of symptoms may occur, and in such an event it is possible that the process of cure is somewhat similar to that obtaining in treatment by suggestion. Though in an impartial analysis the physician should be little more than a recording machine, it is extremely difficult for him to avoid making, or at least being the occasion of, suggestions. The patient seeks a cure at the hands of one whom he regards as

having special knowledge; he is hopeful of a good result and is prepared to act upon the advice proffered. In a multitude of cases such factors seem to constitute the essentials of the cure, while the subsequent particularity of method is but of secondary importance; and however much analysis may scorn suggestion, and it does so quite ostensibly, it, like other methods, can hardly hope to escape such vitiations of its pure practice. In analysis the patient must necessarily feel a more than ordinary degree of confidence in one to whom, through a species of psychic vivisection undergone by himself, he is prepared to reveal such facts about himself as the penitent reveals only under the safeguards of the seal of confession, and indeed possibly to go further and reveal much more that is revolting and that is not present in consciousness. Such confidence in itself implies a faith which would move mountains and a mental state singularly receptive of suggestion. From deductions based upon their experience some analysts regard an examination as incomplete until and unless a sexual complex has been discovered. This probably accounts, at least in part, for the fact that the time occupied runs sometimes into years, and that even then the results are not wholly illuminating and satisfactory: while it almost certainly does account for an unfortunate persistence of thought along sexual lines which sometimes develops in patients treated by this method. It is, however, in the detailed elaboration of investigation and in the consequent establishment of unsuspected relationships between ideas and trends of thought and action that the undisputed merit of later psychological methods is to be found. Hitherto psychological examination of the normal mind has for the most part been by the subject of the subject, that is, the subject has been artificially objectified by itself; while examination of the abnormal mind has mostly been confined to the conscious superficialities. Analysis has made examination both of the normal and of the abnormal a definite study of objective mental phenomena.

Many diseases in general and many functional nervous disorders and mental affections in particular get better or well by a natural process of cure, and it is difficult to distinguish among the antecedents of the process of betterment those which especially have a causal relationship with it. Some such are artificial and have been devised on various grounds,—religious, magical, philosophical and scientific,—for therapeutic purposes; but the essential difficulties in therapeutics are to determine the efficacy of such artificially introduced antecedents and whether the desired result might have been attained without them. Hence the remarkable discrepancies of opinion as to the value of modes of treatment, even when they have been originated and practised by those trained in scientific method and of ample knowledge. The frequent apparent absence of adequate physical factors in the causation of many functional nervous and mental diseases, the dualism which distinguishes between the spheres of action of mind and body, and the apparent potency of the psychic activities of one person directed upon the mental state of another, combine to justify the practice of psychotherapeutics. Nevertheless, even with a proper respect for most recent developments, it is still difficult to be sure as to which is the most successful method, or whether a combination of physico- and psychotherapeutics may not be better than either alone. It is strange to note how exceedingly exclusive the methods of therapy are apt to be. Those who perform miracles or heal by processes such as those of Christian Science claim no technical skill in medical diagnosis or any regard for it, but variation in treatment according to variation in diagnosis or at least according to the various aetiological factors discovered might be expected from the scientifically trained. Nevertheless too frequently the persuasionist, the hypnotist or the analyst apply their methods, much in the way that their precursors of long ago applied their *nostra*, with entire lack of discrimination. Perhaps lying behind their particular methods there is a common factor, one of personal influence, in which certain outstanding practitioners excel and which the remainder conspicuously lack. That there is such a factor is apparent when an ignorant practitioner is seen to be highly successful and one who is learned to be unsuccessful.

In truth, however, the nature of this influence, like so many of the antecedents of improvement in cases of functional nervous and mental disorders, is at present unknown. There must be a very considerable advance before we obtain accurate knowledge of the relative value of the many therapeutic factors that are perhaps concerned. At present treatment is largely haphazard, and improvement is ascribed to the treatment, if any, immediately preceding it; treatment which, maybe, has nothing whatever to do with the improvement that occurs.

LITERATURE.—The most important works on psycho-analysis are four by S. Freud, the most prominent investigator of the subject, translated for English readers by Brill: *Collected Papers on Hysteria* (1912), *The Interpretation of Dreams* (1913), *The Psychopathology of Everyday Life* (1914) and *Three Contributions to the Theory of Sex* (1918). Brill has given a good account of these in his *Psycho-analysis*. Jung's deviation from Freud's position is set forth in *Collected Papers on Analytical Psychology*, edited by Constance E. Long (1917). *Dream Psychology* by M. Nicoll (1920) expounds an interpretation of dreams of a less sexual character than that given by Freud. P. Janet criticised the methods and findings of psycho-analysis in his report to the 17th International Congress of Medicine (*Proceedings of the Congress*, Sect. 12, pt. 1, p. 13). This criticism is somewhat elaborated in Janet's *Les Médications Psychologiques* (1919). On hypnotism the following works are good and ample: J. M. Bramwell, *Hypnotism* (1913); A. Forel, *Hypnotisme* (tr. by H. W. Armit 1906); C. Lloyd Tuckey, *Treatments by Hypnotism and Suggestion* (7th ed. 1921). On persuasion the following may be commended: Paul Dubois, *De l'Influence de l'Esprit sur le Corps* (Engl. tr. 1910) and *L'Education de Soi-même* (Eng. tr. 1911); J. Camus and P. Pagniez, *Isolément et Psychothérapie* (1904); J. Déjerine and E. Gauckler, *Psychonévroses* (1911). A book from a distinctively Christian point of view is the *Spiritual Director and Physician* by Rev. V. Raymond, tr. by Dom Aloysius Smith (1914). (E. D. M.)

PUBLIC ASSISTANCE.—A marked feature in the social-economic history of the 20th century, and one which became even more marked in its second decade, has been the growth in public expenditure in relief of private wants. "Public Assistance" is of two kinds, direct and indirect. Direct public assistance is the receipt of any benefit in money or in kind at the expense of the rates or taxes which is wholly or partly unpaid for by the recipient. Direct public assistance includes objects like old-age pensions, unemployed benefit, children's meals and medical assistance. Indirect public assistance includes cheap baths and wash-houses, main drainage, cheap railway tickets, sanitary inspection and regulation generally, the control and maintenance of water supply and roads. It is with direct public assistance only that this article deals.

In the form of general doles, public assistance has always exercised a most disastrous influence on the countries where it prevailed. In the ancient world the State was founded on slavery and the citizens were a minority. In Athens the payment of citizens for attendance at the public assemblies and religious ceremonies known as the *theoric fund*, exercised a corrupting influence on the democracy from the time of Pericles, and Aristotle lays down the general proposition: "Demagogues distribute surplus revenue to the poor. These receive them and are again in want. For such help to the poor is like 'the cask with holes in it.'" The free distribution of corn at Rome had the same results. At first it was sold cheap to the poor in 121 B.C.; then in 58 B.C. it was made free. At first only one-eighth of the citizens took part in the distribution, but within little more than a decade the proportion had increased six-fold, and the number reached 320,000. Cæsar reduced the number to 150,000, but in Augustus' time it rose again, and the rise continued till as Gibbon relates "in the age which preceded the fall of the Republic only 2,000 citizens were possessed of an independent substance." When the imperial granaries, namely Sicily and Carthage, were lost, the wretched people, by this time quite destitute of self-help and self-reliance, were thrown back upon voluntary charity and the Church.

GREAT BRITAIN.—In modern times England has been the "classic land" for State-regulated public assistance. The system dates from 1601, the 43rd year of the reign of Elizabeth. During the Middle Ages the poorer classes depended on the feudal chiefs and the Church. As the feudal system decayed the poor fell back on the ecclesiastical foundations, and in the oft-quoted

words of Fuller, the abbey "dispensed mistaken charity, promiscuously entertaining some who did and many who did not desire it: yea! these abbey did but support the poor whom they themselves had made." With the dissolution of these abbey these poor people were thrown back on the State, and under the Statute of Elizabeth, which lasted unimpaired till 1834 and in 1921 was still the basis of the Poor Law, a compulsory assessment was made "for the relief of the impotent and the setting of the able-bodied to work." (See under CHARITY and CHARITIES, 5.880 seq.)

The administration of the Poor Law proceeded for 230 years with variations of leniency and severity till 1785, when a period of excessive expenditure set in, which in some cases swallowed up the whole of the annual rateable value of the land and reduced the nation to the verge of bankruptcy, leaving the population in a state of complete demoralization. In 20 years from 1783 the Poor Law expenditure had more than doubled itself, and in 1817 it had reached the enormous total of £7,871,811 for a population of about 11,000,000. In 1832 a Royal Commission was appointed which conducted a thorough inquiry and collected striking evidence on the moral deterioration. It appeared from the evidence that the change made in the character and habits of the poor by once receiving public relief is quite remarkable. They are demoralized ever afterwards. "The disease is hereditary," it was contended, "and when once a family has applied for relief they are pressed down for ever." The receipt of relief by a man has been compared in its results to the loss of virtue in a woman. They are never the same again. The commissioners state that pauperism seems to be an engine for the purpose of disconnecting each member of the family from all others: of reducing all to the state of domesticated animals fed, lodged and provided for by the parish without mutual dependence or mutual interest.

The Commissioners showed that the bulk of the abuses and evils disclosed were the direct result of indiscriminate outdoor relief. They laid down the principles: (1) that the pauper's condition shall be less eligible than that of the independent labourer of the lowest class who has to bear the charge; (2) that the function of the State should be limited to the relief of destitution, such destitution to be tested by the willingness to enter a workhouse or institution; (3) that remedial relief as opposed to the relief of destitution should be left to voluntary charity. The main truth is that in all public relief there must be an element of deterrence and some check or test to prevent general pauperism.

On these principles the new Poor Law, the administration of which was handed over to the Commissioners, was based, and it was exercised with such efficiency that in 1871 with a population of 22,500,000 the cost was almost exactly the same as in 1817 with a population of 11,000,000; in other words the cost of pauperism per head of the population had sunk from 14s. to 7s. Between 1873 and 1883 the percentage of those in receipt of direct public assistance was slightly over 3% of the population, the lowest point reached being 2.9 in 1878 and 1879. In the meanwhile the working-classes had not only recovered their self-respect and self-reliance but had through their own organization, the trade unions, the friendly societies, the coöperative societies and the building societies, provided a complete answer to all the difficulties of the Labour problem. In these trade unions and friendly societies they themselves without help from the State had elaborated methods by which provision was made for sickness, accident and old age. Their coöperative societies provided them with the necessities of life of excellent quality at little over cost price; their building societies provided them with the means to acquire their own houses. At the beginning of the 'nineties a complete survey of the whole problem was taken by the Royal Commission on Labour, and it appeared that the income of 542 trade unions was £1,790,000 and the membership 1,080,000. There were 29,742 friendly societies with a membership of 8,320,262 and funds of more than £26,000,000; also 1,624 coöperative societies with 1,119,000 members and £17,000,000 capital; the sale of foods amounted to £48,500,000 and the profits to £4,774,000; while the assets of the building societies

(£50,700,000) brought the total capital funds traceable to the working-classes up to between £90,000,000 and £100,000,000, quite apart from their deposits in savings banks, etc., which a competent authority estimated at another £160,000,000 at the very least. So different was the position that Mr. Ludlow (the chief registrar of the friendly societies) could say in his evidence before the Commission: "Now the black spots in the country may I think almost be counted on the fingers. In former days it was very nearly black, with but few white spots." This wonderful development of self-help embraced all skilled labour and was gradually taking hold of the unskilled, giving the English working-man a knowledge of business and a training in self-government such as the working-man in no other non-English speaking country possessed in anything like the same degree, if at all.

The serpent however was in the grass. The politicians saw capital in the working-man as a voter. In 1886 the first breach was made in the Poor Law system by the institution of municipal distress committees which withdrew the unemployed to a certain extent from the workhouse test. In 1890 the fees for elementary education were remitted, that the poor might have more wherewith to pay for the food and clothing of their children, but it was not till the beginning of the 20th century that, to use Aristotle's expression, more holes were made in the cask. In 1905 the Unemployed Workmen's Act was passed. In 1906 the Children's Meals Provision Act was passed, in 1907 the Administrative Provisions Act, in 1908 Old Age Pensions were adopted and in 1911 the system of National Health Insurance was introduced with its famous bribe of "9d. for 4d." By 1913 it was no longer possible to form any idea of what proportion of the population was living on its exertions and what was depending on public subsidy, or what was the administrative cost. In January of that year therefore, the writer, with the support of friends on both sides of politics, began to ask for a return which would give the facts and figures. In 1919 the fourth edition of that return was published, and later information enables the following picture to be given in 1921.

In 1890 the expenditure on public assistance from rates and taxes was £25,000,000, in 1901 £40,000,000, in 1911 £68,800,000, in 1919 £172,800,000 according to a return which includes figures as old as 1916 (No. 160, 1920), and for the year ending March 31 1921 no less than £332,000,000 (including war pensions) as far as can be gathered from statements in Parliament. The beneficiaries from the last-mentioned return appear to number not fewer than 28,000,000 out of a population which cannot be put higher than 48,000,000. In other words 58% of the population in 1921 were receiving help from public funds, at a rate of about 6 11s. per head, as compared with 4.6% at a rate of 7s. per head in 1871.

With regard to the total of 28,000,000, on the one hand there is, as will be seen, a great deal of fraud and overlapping which may tend to reduce the number, but on the other hand there are a great many gaps in the figures of the return, the figures relating to the National Insurance Unemployment Act being given at 58,000—much too few for the year ending March 31 1921.

We must now say a few words as to some of the holes in the cask, and on the means, if any, of regulating the money poured in or stopping the leaks.

The principal British Acts concerned are (1) the Education Act with the Provision of Meals Acts, etc.; (2) the Old Age Pension Acts; (3) the National Health Insurance Acts; (4) the Public Health Act, (a) as to hospitals and treatment of disease, (b) as to maternity and child welfare; (5) War Pensions and Ministry of Pensions Acts; (6) Housing of the Working Class Acts; (7) Acts relating to the relief of the poor; (8) Unemployed Workmen's Act; (9) Unemployed Insurance Act. No account is here taken of the bread, coal and railway subsidies, which amounted in 1920-1 to about £87,000,000; they are omitted because they affected the whole population and were temporary.

The Education Act would not at first sight seem to fall under the heading of public assistance, but educationists take an entirely new view of their work to that of other days. "Formerly," says an education report of the London County Council in 1910,

"education was in the main confined (x) to the growth of character, (2) to the growth of the mind. Now it looks increasingly at the social problems which present themselves for solution in the case of the individual child, the problem of physical deterioration, of under-feeding, of impoverished homes and unsuitable employment." In regard to necessitous children, the same authority remarks: "Necessitous children are not necessarily ill-nourished at the time of application, though they would become so if relief were withheld." Not a word is said about the duties of the parent. The same is true of the Public Health Acts, the administrators of which do not consider the character of the individual, but solely the health point of view.

With regard to the vast expenditure under the Education Acts, the select committee on national expenditure reported in Dec. 1918 that they had been impressed by the atmosphere of financial laxity in which questions involving education are apt to be considered, and state that under the Act of 1918 neither Parliament nor the Board of Education nor the local authorities can control education.

With regard to the Old Age Pensions Acts which were to diminish Poor Law expenditure and empty the workhouses, the minister who introduced the proposal in 1908 stated that no Chancellor of the Exchequer in his senses would think of adding £3,000,000 to the sum of £6,000,000 which he proposed. In 1921 the amount voted was £28,000,000, and a proposal to add £15,000,000 thereto was only defeated by a majority of 12, the proposer stating that this was but an instalment and that he was in favour of raising the amount of the pension from 10s. to 20s. and reducing the pensionable age from 70 to 60. As to the administration of those Acts it is noteworthy that Ireland with a pop. of 4,390,000 drew £3,329,000 for 181,000 pensioners, while Scotland with a pop. of 4,760,000 drew £1,664,000 for 90,000 pensioners. This looks as if there was a leak somewhere.

Old-age pensioners have from the first received medical relief from the Poor Law, and now, if necessitous, are entitled to receive other relief as well. The separation of the local administration from that of the Poor Law for political reasons has had unsatisfactory results, apart from the extra expense.

With regard to the administration of the National Health Insurance Act, Sir Arthur Newsholme, a well-known authority, has stated that "the system is not actuarially, financially or medically sound, and has involved expenditures in administration entirely incommensurate with the benefit received."

The overlapping of the insurance system with the Poor Law has involved endless difficulties, and it appears from the Return No. 160 (1920) that the annual expenditure for the year given (1919 is the latest available) was £4,204,000 out of a total expenditure of £20,311,000. It was stated as long ago as 1912 that overcoats, underclothing and food were given under sanatorium benefit, thus relieving public health and Poor Law funds, and sanatorium benefit was only a rechristened form of outdoor relief. As to the Poor Law, it may be observed in passing that its expense increased between the years 1911 and 1919 from £15,000,000 to £18,000,000 for England and Wales alone, and as old-age pensioners left the workhouse their places were filled by those under 70 years of age.

With regard to the unemployed insurance it appears that the reserve of £20,000,000 which existed after the World War was exhausted by June 1921, and that the Treasury was drawn upon for another £10,000,000, while as to the unemployed dole the magistrate at the Thames police court on May 18 1921 said: "It has been said from this bench over and over again that such doles lend themselves to and almost induce fraud."

All that can be said with certainty as to the national housing scheme is that the losses to the central and local Government on each house annually will amount to an enormous sum. Originally 1,000,000 houses were to be built. In May 1921 the annual loss to the State on each house was placed officially at £60 apart from local rates. This makes an annual loss of about £18,000,000, or a total eventual loss at the end of 60 years of £720,000,000. Thus a privileged class of house-holders will be created at an enormous loss.

The attitude of Parliament to such expenditure gives little hope of a check from that quarter. There is a constant complaint of the apathy and slight attendance at debates on economy, and the late Speaker of the House of Commons pointed out that since 1900 there has been a great change in the attitude of the House towards economy and that now the advocates of economy "do not get a look in." The Chancellor of the Exchequer frankly said in March 1920 that with such items as old-age pensions, a national unemployment scheme and a national housing scheme, it was impossible to offer a blunt uncompromising refusal to proposals for new expenditure.

With regard to the central authority, economy is unlikely from that direction, for enormous increases have been made either in the shape of additional salary or temporary bonus by Whitley Councils consisting of civil servants to the lower grades and by the Government to the higher grades (including the Treasury), which in both cases, without previous knowledge or sanction of Parliament, the central authority has by circular invited local authorities to follow, and the central authority has a means in the Exchequer grants (which it can give or withhold at will) for stirring up the local authority to spend money.

On the whole then, there seem few weapons in the hands of those who would stop the progress of a democratic nation on the road to ruin. But they comprise, first, a complete statement of accounts showing how the money is raised, how it is spent, what is the administrative cost and who are the beneficiaries, whether worthy or unworthy. Secondly, the institution of a strong but small central commission, as in 1832, to ration the administration of the whole of the new system of public assistance, taking care not only to punish fraud and put down overlapping but also to make the position of the beneficiaries (apart from war pensioners) less eligible than that of the lowest class of independent workmen, and introduce some stringent and deterrent test. Lastly, to make it clear that all this vast expenditure from the rates and taxes, however carefully disguised, falls in the long run most heavily on the working-classes, by wasting the fund from which come new enterprises and increased wages on myriads of officials who make the poor man's life a burden to him.

(G. DR.)

UNITED STATES.—Owing to the fact that the United States is still a new country with a comparatively small number of poor, the need in its communities for public assistance in the relief of poverty and attendant ills has been much less urgent than in European countries. One consequence is that the "right to relief" has been recognized in the laws of only a few of the states. That every man ought to support himself and his family is, or has been, the working social theory of Americans of all classes. They have looked with disfavour on continued subsidies and other payments which might seem to be part of a routine, preferring to provide temporary assistance when necessary, treating each case as an emergency, in the expectation that the beneficiary will soon be able to shift for himself. They have declined to recognize formally the existence of a necessitous class. Hence much of the relief work in the United States up to 1921 was still done by privately supported agencies.

In the decade 1910-20 it became obvious, however, that a change had begun. Americans seemed to be losing their aversion to paternalistic government, and the newer proposals for social betterment tended to call for some kind of legislation involving an extension of state or municipal activity and for an appropriation. Among the more progressive states and cities it became the rule to establish departments of public welfare, which, though their duties and perhaps their theories were somewhat vague, nevertheless made incessant demands for further appropriations and for fresh welfare legislation. It is characteristic of the American point of view, however, that this welfare movement concerned itself less with the lowest forms of poverty or with the most helpless layer of the dependent than with improving the conditions of life among wage-earners in general.

The tendency to extend the range of Government activity in welfare work did not escape serious criticism. This criticism was perhaps most emphatic with respect to the ever-widening

PUBLIC ASSISTANCE

211

scope of the work undertaken by public health departments. The point was made that in so far as these bodies exceeded the limit of indispensable activities they were "pauperizing" the public. The accepted view was that the duty of sanitary authorities was not to help any one family to be healthy, but to prevent any one family from disseminating disease. But it is almost impossible to draw a line between necessary functions and those which are largely philanthropic. Thus many cities maintained a large staff of physicians and nurses whose duty it was to visit schools and even households, giving advice and treatment free. From the private practitioner's point of view this work was an encroachment on his legitimate sources of income, but free medical treatment in the case of school-children, for example, is merely an incident of free education, for the ability to receive education is in large degree dependent on physical fitness. It should be said, moreover, that in most cities free treatment was not given unless the recipient was unable to pay, and that in any case the community was only protecting itself by promoting the health of its individual members. The same question was involved in the establishment of sanatoriums in many parts of the United States for the treatment of tuberculosis and other communicable diseases, both aiding the sufferer and safeguarding the public from him, as had been done in the case of the insane for many years. In some of such institutions a nominal charge was made, but by far the greater part of the expense was paid by taxation. Hospitalization came to be expected as a right, regardless of the ability of the patient to pay the cost of treatment. Thus the American public was being taught to feel that the state or county or city was bound to provide certain kinds of public assistance which had been regarded as outside the scope of state subsidies.

Of the newer proposals for public assistance none gained more rapid headway than that for mothers' allowances or pensions. The first such law was passed by Missouri in 1911, and granted allowances to widows with children and to deserted mothers; by 1920 there were similar provisions in 39 states. These allowances ranged from \$2 a week for each child up to \$25 a month for the first child and \$15 a month for each additional child. The age limit, after which the allowance was to cease, was placed at 13 years in some states and as high as 18 in others. Up to 1920 the aggregate of these allowances had not become so large as to alarm taxpayers, and in so far as the system saved the children from being committed to public institutions— orphan asylums and the like—it was undoubtedly beneficial. Legislation for mothers' allowances, no doubt, tends to create a demand for old-age pensions, but up to 1921 no state had yet undertaken this form of subsidy. Taxes for mothers' allowances were mostly levied and administered by the county governments.

Another form of public assistance which grew rapidly in the decade 1910-20 was that connected with the health of children, particularly those attending school. As early as 1892 New York City provided for the inspection by health officers of school-children, and by 1920 practically every city had organized some form of health examination for all pupils attending public schools. In later years the scope of the work was considerably expanded; skilled medical examiners were employed to give especial attention to eyes, throats and teeth, and, where necessary, treatment was often given at public expense. Special open-air schools were opened in many places for tubercular children; and proper conditions maintained for giving the children adequate fresh air, rest and nourishment. In many poorer districts, where the educational progress of the children was found to be retarded by under-nourishment, it became customary for the school authorities to provide a daily luncheon, which was served either free or at a nominal price. In 1919 cities having each a pop. of more than 30,000 expended an aggregate of \$1,849,624 on medical work for school-children, and an additional amount of \$908,742 on other child conservation work, such as the employment of trained nurses to visit mothers in congested districts and the establishment of infant welfare stations where mothers could obtain medical advice and free treatment for their babies.

To determine the aggregate amount of public assistance in the United States it is necessary to state that such items as those for sanitation, prevention of epidemics, protection to life and property cannot properly be regarded as public assistance. The following tables, based on U.S. Census Bureau reports, show the increase in public expenditures in the period 1913-9 for health conservation and maintenance of charities, hospitals and correctional institutions:—

HEALTH CONSERVATION			
Expended by	1919	1913	
States	\$12,249,333 (1918)	\$ 6,388,114	
Counties	5,000,000 (est.)	2,815,466	
Cities	20,208,615	12,000,000 (est.)	
Total	\$37,457,948	\$21,203,580	
CHARITIES, HOSPITALS AND CORRECTIONS			
States	\$118,084,025 (1918)	\$ 87,585,903	
Counties	60,000,000 (est.)	37,815,508	
Cities	55,086,145	32,896,351	
Total	\$233,170,170	\$158,297,762	
Grand total . .	\$270,628,118	\$179,501,342	

Thus the increase in expenditures for the purposes noted was somewhat more than \$90,000,000 in six years. These figures, however, include the cost of certain activities which cannot rightly be classed as public assistance, and which are approximately one-third of the total. With respect to the more recent compilations of the Census Bureau, it is possible, because of the greater fullness of data, to exclude those items. Thus a tabulation of the expenditures by the states for public assistance in 1918 would include the following:—

HEALTH CONSERVATION.	
Treatment of tuberculosis—	
In institutions	\$5,105,556
Elsewhere	643,981
Treatment of other communicable diseases	1,488,186
Conservation of child life	285,674
Other health activities	764,497
CHARITIES AND HOSPITALS.	
Supervision	849,727
Outdoor relief	517,827
Care of poor—	
In state institutions	211,995
Elsewhere	121,101
Care of children—	
In state institutions	1,328,441
Elsewhere	2,023,205
Care of blind, deaf and mute—	
In state institutions	4,458,758
Elsewhere	1,713,274
Other charities—	
State institutions	8,924,208
All other	530,862
Hospitals—	
General	2,613,951
All other	3,149,100
Hospitals for the insane—	
State	47,860,528
All other	2,091,304
Total	\$84,682,175
The expenditures of cities for similar purposes in 1919 were as follows:	
Prevention and treatment of communicable diseases—	
Tuberculosis	\$5,145,280
Other communicable diseases in hospitals	4,427,510
Other treatment	2,271,364
Conservation of child life—	
Medical work for school-children	1,849,624
Other child conservation work	908,742
Charities and hospitals—	
General supervision	854,466
Outdoor poor relief	4,631,697
Poor in institutions	7,715,940
Care of children	7,125,436
Other charities	3,570,051
General hospitals	16,735,615
Insane hospitals	3,871,082
Welfare commissions	47,307
Total	\$59,154,114

PUBLIC TRUSTEE

With respect to conservation of health, items representing general administrative expenses have not been included in the two preceding tables, although a certain percentage of these undoubtedly belongs under the heading "public assistance." Whatever their amount may be it is offset by the unavoidable inclusion of certain expenditures for preventive health measures, most of which are undertaken for the benefit of the community at large rather than with the definite purpose of aiding needy persons. Detailed figures showing the expenditure of counties were not available, and it is possible that if the aggregate expenditure for mothers' allowances were known, it would materially increase the totals given in this article.

The available data indicate that, exclusive of Federal provision for former soldiers and their families, and for other agencies for dependents which come under the jurisdiction of the Federal Government, the total expenditure for public assistance in the United States in 1920 was more than \$200,000,000, the appropriations originating as follows: states, \$90,000,000; counties, \$45,000,000; and cities, \$65,000,000. It seemed probable that these appropriations would rapidly increase as the more recent projects for public assistance became more fully developed and as the economic reaction following the World War spent itself.

(F. H. H.)

PUBLIC TRUSTEE (see 27,334).—The Office of the Public Trustee, created in Great Britain by the Public Trustee Act 1906, was opened at Clement's Inn, London, on Oct. 1 1907, under Sir Charles John Stewart, K.B.E. (1918), who organized and controlled the Department during a period of rapid growth until his retirement in 1919. He was succeeded in office by Mr. Oswald Richard Arthur Simpkin, to whom fell the equally difficult task of post-war reorganization. The other principal officers of the Department in 1921 were Mr. Ernest King Allen, Assistant Public Trustee (at Kingsway), and Mr. Thomas Moffat Young, Deputy Public Trustee, at Manchester. The staff in 1921 numbered 874 in London and 86 at Manchester.

The number of trusts and estates accepted for administration by the Public Trustee in the first year (1907-8) was 63, valued at £384,000. In 1913-4 the acceptances were 1,573 cases valued at £13,500,000, and at the end of that period the Office was administering 5,480 cases, representing a value of £43,500,000, and had distributed 450 cases and £5,834,691 of trust funds. Meanwhile the staff had grown in number from 19 to 370, the annual fee income from £502 to £55,283, and the expenses from £3,312 to £40,428. On April 1 1914 a Northern Branch of the Department was opened at Manchester (Northern Assurance Buildings, Albert Square) under a Deputy Public Trustee, and following on the Report of the Royal Commission on the Civil Service the Public Trustee's staff was made a part of the permanent Civil Service.

The outbreak of the World War found the Department manned almost entirely by officials of military age, and probably no Government Office suffered so much from the transfer of members of its staff to the fighting services. During the greater part of the war period most of its work had to be done by women clerks and by such temporary men as could be recruited under the existing conditions. In Sept. 1914 new and onerous duties were laid upon the Public Trustee by his appointment under the Trading with the Enemy Act and Proclamation as Custodian for England and Wales of enemy property. The Act provided that all sums payable to enemies by way of interest, dividends or share of profits should be paid over to the Custodian; that firms with enemy partners and companies with enemy shareholders should make returns to the Custodian disclosing such enemy interests, and that all persons holding or managing property on account of enemies should give particulars to the Custodian. Under the Patents and Designs Act 1907, the Public Trustee was also appointed to receive royalties in respect of patents avoided or suspended under the Patents, etc., Temporary Rules Act 1914. A separate "Trading with the Enemy" Branch was opened at 2, Clement's Inn on Nov. 30 1914. Further legislation in 1915, 1916 and 1917, and also the Peace Treaty, threw additional duties upon it, and in 1921 it employed a special

staff of 327 persons at Kingsway and Cornwall House. The fees collected by the Public Trustee as Custodian from 1914 to 1921 amounted to £412,000.

In 1915 the Public Trustee Office was removed from Clement's Inn to new Government buildings in Kingsway, Sardinia Street, and Lincoln's Inn Fields, but the continued growth of the work and staff made it necessary to invade the adjoining buildings, Queen's House and Victory House.

The progress made during and after the war is indicated by the following table:—

Cases Accepted	Value	Fees	Expenses
1914-15 . . . 1,543	£11,624,000	£65,390	£61,632
1915-16 . . . 1,595	16,622,000	74,762	72,171
1916-17 . . . 1,811	16,544,000	95,238	98,330
1917-18 . . . 1,876	17,862,000	107,139	130,457
1918-19 . . . 1,767	17,192,000	119,619	175,881
1919-20 . . . 1,950	21,864,000	148,756	241,787
1920-21 . . . 1,559	15,682,492	283,499	398,389
Total since Oct. 1 1907 . . . 18,030	166,164,701	1,074,109	1,345,652

Two facts stand out conspicuously from this record. The first is the large business annually brought to the Department by a "voluntary" public and the very large number and value of the estates under the Public Trustee's care. The second is that whereas the Department was apparently self-supporting from 1907 to 1916, after 1916 the fees earned under the Public Trustee Act were insufficient by an increasing margin to cover the cost of the work done under that Act. The explanation in a nutshell is that the scale of fees which was in force until April 1920 was nicely calculated to cover (without a profit) the cost of staffing, housing and working the Department under the conditions which existed before the war, with a non-pensionable staff of young men who were content to look to the future of a rapidly growing office, rather than to the immediate present, for adequate pay. Such a scale of fees was bound to prove too low when the Department had to pay (in part) the salaries of an absent staff as well as those of their temporary substitutes, to make provision for pensions, to meet the charges for larger and more expensive buildings, completely to reorganize its personnel after the war on an entirely new basis of salary values, and finally to conform with the new and much more generous treatment of Civil Servants in the matter of base salaries and "cost-of-living" bonus which followed the institution of Whitley Councils in the public service.

On the retirement of Sir Charles Stewart the Lord Chancellor appointed in April 1919 a strong Committee, with Sir George Murray, G.C.B., as chairman, to review the whole position of the Department and to report upon questions of staffing, pay, policy, decentralization and fees, and it did so in Nov. 1919. With one dissentient the Committee approved the general lines on which the office had hitherto been conducted and recommended as a basic policy that "trust estates should, while retaining the service of outside agencies, secure the further advantages afforded by a Public Department having at its disposal within its own walls independent experts capable of criticizing and possibly correcting or supplementing the advice received through the ordinary channels available to the private trustee." The Committee recommended the modification and strengthening of the internal organization in certain respects, and in order to restore the financial equilibrium, upset by the war, suggested a new scale of fees calculated to increase the income of the Department by about £120,000 a year. With regard to branch offices, the Committee recognized the successful and economical management of the Manchester office and approved the principle of decentralization, but hesitated to recommend further experiments in this direction "until the possible deterrent effect of the increased fees on new business has been ascertained." Mr. S. Garrett in his Minority Report advocated a restricted service and somewhat lower charges, and doubted whether "business would be obtained in the provinces at the fees proposed by the Majority Report." The Majority Report was accepted by the Lord Chancellor, and the new scale of fees became operative on April 1 1920.

The increase of fees was still too recent in 1921 for its effects to be accurately measured, and the calculations upon which it was framed had already been to some extent upset by unforeseen circumstances. It remained to be seen whether Civil Service conditions strictly applied to a Department which, like the postal, telegraph and telephone services, was essentially a business undertaking, but unlike them was not a monopoly, were compatible with commercial success in a field open to competition. The competitors of the Public Trustee are (a) banks, insurance companies and other corporate trustees, and (b) solicitors, who are the active managers of thousands of trusts and estates nominally administered by others. If the Public Trustee's charges were to rise beyond a certain level his services would not be sought, and his competitors, who as employers are entirely untrammelled, would be greatly stimulated and assisted. In 1921 there was as yet no indication that this level had been reached, and those who resorted to the Department had at any rate the satisfaction of

knowing that the Public Trustee's fees, if and when they showed a commercial profit, would be reduced.

On the administrative side the Public Trustee Office may be regarded as an established success and an institution of great public utility in protecting beneficiaries against the loss of trust funds through incompetence and dishonesty. Its work has been brought up to a high standard of efficiency, and the system of organization under which every trust is administered by an individual trust officer, who is personally responsible for its proper conduct, disarms the criticism that the functions of a private trustee cannot be performed by a department of the State. Another ear, viz. that the aggregation of a vast body of investments under the control of a single official might be a public danger, has found no justification in experience. Although the Public Trustee is responsible for investments of one kind and another (apart from "enemy" property) of a nominal value exceeding (in 1921) £143,000,000, they are in fact so multitudinous in character, represented by so many separate earmarked holdings, governed by so many different trust instruments, and in so many cases controlled jointly by co-trustees, that it would be impossible to deal with them *en masse*. As a further safeguard the Public Trustee, from 1914 onwards, has enjoyed the advantage of the counsel of an Investment Advisory Committee composed of representatives of finance in the City of London; in 1921 it consisted of the Rt. Hon. Frederick Huth Jackson, Mr. R. Martin-Holland, C.B., Sir R. M. Kindersley, B.B.E., and Mr. J. A. Mullens, Junr. This Committee meets monthly to review and discuss with the Public Trustee all investments and sales for reinvestment made by him.

Public Trustee in Other Countries.—The first country to possess a Public Trustee was New Zealand (1872), and the Public Trustee of New Zealand had in 1921 offices at Auckland, Christchurch, Dunedin and Wellington. In Australia there are Public Trustees at Sydney (N.S.W.), Adelaide (S.A.), and Hobart (Tasmania), and Public Curators (with similar functions) at Melbourne (Victoria), and Brisbane (Queensland). In Canada there is a Public Trustee at Toronto. In India and Burma there are Administrators-General and Official Trustees (offices at Allahabad, Bombay, Calcutta, Madras and Rangoon) who have some of the functions of the Public Trustee in England. Ireland has a Public Trustee (at Dublin), who receives only purchase moneys paid under the Irish Land Acts.

PUCCINI, GIACOMO (1858—), Italian composer (*see* 22,632). His recent works include *La Fanciulla del West* (*The Girl of the Golden West*, 1910); *Le Rondine* (1916); *Il Tabarro*, *Suor Angelica*, and *Gianni Schicchi* (1918).

PULITZER, JOSEPH (1847-1911), American editor and newspaper proprietor, was born in Budapest, Hungary, April 10 1847. He came to America in 1864, entered the Union Army, and served to the end of the Civil War. In 1868 he became a reporter on the *Westliche Post*, a German newspaper in St. Louis, and in 1871 managing editor and part owner. In 1869 he was elected to the Missouri House of Representatives; in 1872 was a delegate to the Liberal Republican National Convention which nominated Horace Greeley for president; and in 1874 was a member of the Missouri Constitutional Convention. In 1876-7, during the Hayes-Tilden controversy, he was in Washington, D.C., as correspondent for the *New York Sun*. In 1878 he purchased the St. Louis *Evening Dispatch* and *Evening Post*, combining them as *Post-Dispatch*. In 1880 he was a delegate to the National Democratic Convention. In 1883 he bought from Jay Gould the *New York World* (*see* 19,560), which fearlessly attacked political corruption. In 1884 he was elected Democratic member of Congress from the state of New York, but resigned after serving a few months. In 1896 he allied himself with the "Gold" Democrats and opposed the nomination of William Jennings Bryan. During his later years he was blind and spent much of his time cruising about the world in his yacht, but to the end continued to direct his *New York* paper. He died on board his yacht in Charleston harbour, S.C., Oct. 29 1911. Interested in improving the profession of journalism, he worked out a plan for establishing a school for training journalists. In 1903 he set aside \$1,000,000 for establishing a school of journalism at Columbia University. His own idea as to the object of such a school is set forth in an article, "The College of Journalism," contributed to the *North American Review* for May 1904. In Sept. 1912 the School of Journalism of Columbia was opened. He left \$500,000 each to the New York Philharmonic Society and the Metropolitan Museum of Art.

His son, RALPH PULITZER (b. 1879), succeeded him in control of his newspaper properties. He married (1905) Miss Frederica Vanderbilt Webb of New York City.

PUTNIK, RADOMIR (1847-1917), Serbian general, was born on Jan. 25 1847 at Kraguyevats. Like many other prominent figures in the life of his country, he came of a family which had emigrated to the Banat during the Turkish conquest and returned to Serbia after the expulsion of the Turks. Passing through the artillery school (which afterwards became the Serbian military academy), he obtained his commission in a line regiment. In 1876 he commanded a brigade in the war against Turkey, and when war was renewed in 1877 became chief-of-staff of the Shumaja Division. In the Serbo-Bulgarian War of 1885 he held a similar post in the Danubian Division, and in 1889 was made deputy-chief of the general staff, and taught as professor at the military academy in Belgrade. Like many other brilliant officers, he suffered from the favouritism which Kings Milan and Alexander had introduced into the Serbian army and from the consequent atmosphere of intrigue and personal rivalry. He was placed on the retired list, and it was only after the military revolution which destroyed the Obrenović dynasty in 1903 that he obtained his real opportunity of service. In that autumn he was appointed general and chief of the general staff. In 1906 he succeeded Gen. Gruić as Minister of War, and again held that office in 1912, during the decisive period when the military convention with Bulgaria was being negotiated. On the outbreak of war with Turkey he was made *vojvoda* or marshal (being the first holder of that title) and commander-in-chief, and was responsible for the rapid success of the Serbian arms at Kumonovo, Prilep and Monastir. It was largely owing to his vigilance and foresight that the treacherous night attack by which the Bulgarians opened the second Balkan War (June 29 1913) was so complete a failure. In the preceding months of suspense he and his staff had worked out a careful plan of action, and when Gen. Savov on July 1 gave his amazing order for the cessation of hostilities, Putnik was able to launch a counter-offensive, which resulted in the long-drawn-out battle of the Bregalnitsa and the final retreat of the Bulgarians. When the World War broke out he was undergoing a cure at an Austrian watering place—a very practical proof that the Serbian High Command was not preparing for an armed conflict. At first placed under arrest, he was released by special order of the Emperor Francis Joseph and conveyed to the Rumanian frontier. His impaired health did not prevent him from resuming the position of Serbian generalissimo and organizing the resistance of the country to invasion; and he inflicted upon the forces of Gen. Potiorek three successive defeats—the battles of the Vadar (Aug. 16-20), of the Drina (Sept. 8-19) and of Rudnik, which ended on Dec. 14 1914 with an Austrian rout and the complete evacuation of Serbia. On the latter occasion Putnik's success was rendered definitive by the genius of Gen. Mišić, the commander of the I. Army. Putnik retained the supreme command during the triple invasion of Serbia by the German, Austro-Hungarian and Bulgarian armies in Nov. 1915, and shared the retreat of the Serbs through Albania. When, however, the exiled Government established itself at Corfu, he and most of his staff were placed on the retired list. He himself withdrew to France. He died on May 17 1917 at Nice.

PUTUMAYO, or ICA (*see* 1,788), one of the larger tributaries of the Upper Amazon, rising in Ecuador in the Cordillera of the Andes, near Pasto, flowing in a S.E. direction and joining the Amazon at a point somewhat S. of lat. 4° S. The middle reaches of the river are also known as the Caquetá, the lower reaches being called the Caquetá or Yapurá. The Putumayo, which gives its name to the whole region through which it flows—a wilderness of tropical forest of which the sovereignty has been long in dispute between the republics of Peru, Ecuador and Colombia—obtained an evil notoriety in 1912 after the publication by the British Government of the Blue Book containing the evidence, collected by Mr. (afterwards Sir Roger) Casement, of the atrocious methods employed in this district by the agents of the Anglo-Peruvian Amazon Rubber Co. in order to force the natives to collect rubber. These crimes, which recalled those of the Congo and covered the whole gamut of hideous atrocity (there were some too horrible to publish

even in the Blue Book), were first denounced in *La Felpa* and *La Sancion*, papers published at Iquitos, in 1907, shortly before the Peruvian firm of Arana Brothers—who had exploited this territory since 1896—was merged in the Anglo-Peruvian Co., with its headquarters in London. It was not, however, till 1909 that the attention of the British Government was directed to this matter by the revelations of Mr. Hardenburger, an American traveller, in the British periodical *Truth*. Since certain British subjects, negroes from Barbadoes, were implicated in these charges, Mr. Casement, then British consul-general at Rio de Janeiro, was commissioned in 1910 to proceed to Iquitos and the Putumayo and institute inquiries on the spot.

As a result of the report submitted by him a Select Committee of the House of Commons investigated the matter, and its report was issued on June 9 1913 as a White Paper (148). This analysed the evidence with great care, and, as the result, decided that Señor Julio C. Arana (who had come over to give evidence), together with other partners of the firm, was responsible for the atrocities committed by his agents in the Putumayo. The Committee, however, was satisfied that he did not communicate his knowledge of them to the British directors of the company before the *Truth* revelations. Those directors were severely censured for culpable negligence in respect of the labour conditions under the company, but it was found that they had not individually laid themselves open to any charge under the Slave Trade Acts. The Committee further reported that existing enactments might be extended so as to cover the gravest offences against the person and against the practices of forced labour which are akin to slavery. A committee, consisting of members of Parliament and others, subsequently met to devise and press forward legislation to this effect; but its labours were interrupted by the outbreak of the World War.

The Putumayo atrocities called attention to the whole system of "loan slavery" and forced labour as practised throughout Latin America. For it was clear that the treatment of the Putumayo Indians was exceptional only in the maddest demonstrations of its inhumanity, and that the slave-driving habit which made it possible was not confined to one region of the continent. The Putumayo region, though vast, is but a small part of the rubber-producing territory of the Amazon; and in all there was evidence that similar conditions prevailed to a greater or less degree. The root of the whole evil was the so-called *patrón* or "peonage" system—a variety of what used to be called in England the "truck system"—by which the employee, forced to buy all his supplies at the employer's store, is kept hopelessly in debt, while by law he is unable to leave his employment until his debt is paid. Not only natives but many foreigners—including British immigrants—have been caught by this system. The *peon* is thus, as often as not, a *de facto* slave; and since in the remoter regions of the vast continent there is no effective government, he is wholly at the mercy of his master. His main safeguard against the worst forms of cruelty is his commercial value; for labour is scarce and, as was said to the present writer by a planter from the Beni in Bolivia, "You do not kill a man who is worth £80."

This safeguard has, however, in effect, proved insufficient; for the rubber-gatherers have been more concerned to make rapid fortunes than to look to the future. One result has been a hideous wastage of labour. In 1906 the Indian population of the Putumayo was estimated to number 50,000; five years later Mr. Casement put it at 10,000 at most; while a writer in the *South American Supplement* of *The Times* (Feb. 25 1913) spoke of the labour difficulty in the Brazilian rubber districts, due to "the dying-out of the native races from disease and bullets."

That the same process of extermination was proceeding in other districts is shown by a pastoral letter "on the amelioration of the actual condition of our Indians," issued on March 14 1913 by Dr. Manuel Polit, Bishop of Cuenca in Ecuador:—

"Our Ecuadorian Oriente has nevertheless not been free from the man-hunts (*corrias*) and outrages of these inhuman traffickers, rubber-gatherers (*caucheros*) and others, who, ascending unhindered our navigable rivers, have despoiled of their poor possessions and of their liberty hundreds of savage Indians, torturing and killing

those who resist. And if formerly the action of our missionaries, supported by the Government, was able to prevent or to remedy a great part of these evils, nowadays, when the missionary has been expelled, the hunters of men can operate unchecked; and the banks of the Napo, Aguarico and Curaray, of the Pastaza, Morona and Santiago, have more than once presented scenes similar to those enacted on the Putumayo."

Similar evidence is given in the reports of Padre Estanislao de Las-Corts, Apostolic Prefect of the Caquetá and founder of the Colombian settlement of Puerto Asis on the upper Putumayo, who speaks of "the arms of the devil for dragging the poor Indians down to hell, some with the title of *corregidor*, others calling themselves doctors, and all in league with the *caucheros*, who style themselves *patrónes*."

In addition to the martyrdom and partial extermination of the Amazon Indians, this savage exploitation of the wealth of the Amazon forests has produced another result—the rapid destruction of the wild rubber trees, tapped by unscientific methods, never replaced, and of late years deliberately destroyed by the Indians as the source of all their woes. Many solutions of the problem have been suggested, of which the most notable is perhaps the proposal of an international control of the whole rubber-producing region by a commission representing the Amazon States, and scientific exploitation of these regions by means of imported Chinese and Japanese labour. There are already Japanese colonies on the upper Amazon, and both Chinese and Japanese mix and intermarry freely with the more civilized native "Indians," whose ultimate affinity with the Mongol race is at least highly probable.

The Putumayo revelations led to movements for reform in Latin America itself. Apart from the devoted work of Capuchin Friars, Marist Fathers and Franciscan Sisters in the Colombian districts of the upper Amazon, by the Salesian Fathers in the recently established diocese of Cuenca in Ecuador, by the community of the "Discalced" Franciscans of Lima in Peru, or by the Franciscan missions of Guarayos in Bolivia,¹ lay effort has not been wanting. In Peru the Sociedad Pro-Indígena de Lima took up the cause of the natives with great zeal, and the Colombian and Bolivian Governments both passed remedial legislation. But the Colombian reforms were necessarily limited in scope—and, indeed, till the international boundaries are fixed all effective reform is impossible—while the Bolivian decree of Nov. 25 1913 regulating "loan slavery" remained a dead letter in a country whose vast distances made any effective supervision impossible. To provide that "all contracts between master and man shall be registered at the nearest police office" is not much use in a country where the police offices are scattered hundreds of miles apart, and "where a journey of 200 m. by launch is a serious undertaking, and much more so when runners and canoes are alone available."

Thompson, *The Putumayo Red Book* (1913), inspired partly by desire to vindicate the Colombian claims to the Putumayo region; Joseph F. Woodroffe, *The Upper Reaches of the Amazon* (1914), the outcome of eight years of personal experience; J. F. Woodroffe and H. H. Smith, *The Rubber Industry of the Amazon* (1915). Several valuable articles on the Amazon rubber industry, the peonage system, etc., were published in *The Times South American Supplement* during 1913 (see index, in the issue of Jan. 27 1914). (W. A. P.)

PYLE, HOWARD (1853–1911), American artist and writer (see 22.679), died in Florence, Italy, Nov. 9 1911.

PYROMETRY (see 22.693).—The term "pyrometer" is now applied to any device intended to measure temperatures beyond

¹ The work of these missions, actively supported by the Government at La Paz, has produced astonishing results. At Urabicha, a "model town," for instance, silverware and jewelry are made, and there are workshops for cutting and polishing ebony to be used in making fine furniture. At Yotau expensive machinery for crushing and refining sugar has been installed. At Ascension carpentry is taught on a large scale. The "Discalced" Franciscans of Lima conduct a flourishing school of agriculture. The Capuchins of Colombia, turned sappers and engineers, constructed a wonderful mule-road over the Andes from Pasto to Mochoa. These and other instances of effective zeal are, however, it must be confessed, exceptions which only serve to heighten by contrast the effect of the inertia of the Church in Latin America.

the upper limit of the mercury thermometer. The success of many metallurgical and other operations carried out in furnaces often depends upon correct regulation of temperature, and for this reason pyrometers are extensively used to control processes conducted at high temperatures. A number of different types of pyrometer are in use, each having its special advantages; and the choice of instrument depends upon the nature of the operation. In order that pyrometers of every pattern may agree in their readings, each is calibrated by reference to a number of fixed points, determined by the gas thermometer. The National Physical Laboratory scale is used in Great Britain, and represents the melting-points or boiling-points of a number of pure materials, chosen so as to be separated by convenient intervals of temperature. Suitable points for graduating pyrometers are the melting-points of zinc (419.4°C.), antimony (630°), common salt (801°), silver (961°), copper (1083°), nickel (1452°) and palladium (1549°). Above 1550°C. direct comparison with the gas scale is not possible at present, and instruments designed to read higher temperatures than this are calibrated by reference to the laws of radiation. The features of the different types may conveniently be considered in separate categories.

Thermo-electric Pyrometers.—These depend upon the electromotive force developed when a junction of two dissimilar metals is heated. The couple used should show a steady increase in E.M.F. with rise in temperature, and should not be destroyed or show an alteration in E.M.F. on prolonged heating. These conditions are best fulfilled by couples made of the platinum series of metals, but owing to the high cost of these, "base" metal couples are now largely used, which can be renewed when necessary at a trifling expense. The upper limit of temperature at which a thermocouple may be used must be some degrees below the point at which destruction or change in E.M.F. would commence. Thermocouples in common use are platinum and rhodium platinum (10% Rh), which may be used to 1400°C. and generates an E.M.F. of 1.1 millivolts per 100°C. ; iron and constantan, upper limit 900°C. , E.M.F. 6.7 millivolts per 100°C. ; and two different nickel-chromium alloys (Hoskin's alloys), upper limit 1100°C. , E.M.F. 7.4 millivolts per 100°C. Various other couples are also used. It will be noted that the base-metal couples develop a much higher E.M.F. than those made from the platinum group. Most couples require protection from furnace gases, which would cause corrosion, and are provided with shields of silica, porcelain, fireclay, or other refractory material, which should be non-porous.

The indicator used with a thermocouple is usually a millivoltmeter, the range of which is determined by the couple used, and the temperature to be measured. The deflections shown when the couple is subjected to the standard temperatures enable the scale to be marked so as to read temperatures directly. Due allowance must be made for the temperature of the other junctions in the circuit, as the deflection, in general, depends upon the excess temperature of the heated junction over the "cold" junction or junctions. Errors in this direction may be avoided by (1) locating the cold junctions in oil in a thermos flask, so as to maintain a constant temperature; (2) by water-cooling the cold junctions; (3) by the use of compensating junctions (Peake and others); or (4) by compensated indicators (Bristol, Paul, Darling and others). For measuring special ranges—such as 500° to 1000° —an opposing E.M.F. from an external source is applied to the indicator, so that deflection does not commence until the junction has attained 500° . Instead of a millivoltmeter, the indicator may take the form of a potentiometer, in which the E.M.F. due to the junction is balanced against a known difference of potential (Northrup, Brown, Rosenhain and others), with the advantages that a delicate galvanometer may be used, and that the indications are independent of the resistance of the leads.

Continuous records of temperature may be obtained by photographic means (Roberts-Austen), a mirror galvanometer being used as indicator, and the spot of light directed on a sensitized paper moving at a known rate. Records in ink are obtained by depressing the pointer of the indicator at regular intervals, and causing it to make a dot in ink on a chart moving at a known rate, thus recording the deflection at any moment. In the "Thread" recorder (Cambridge and Paul Instrument Co.) an inked thread is pressed onto the chart; in Siemens' and Paul's recorders an inked ribbon is made to touch the paper; in Foster's recorder a special pen, at the end of the pointer, makes the dot. Recorders may be actuated by clock-work or electric motors.

The present practice is to employ thermo-electric pyrometers for all ordinary work up to 1100 or 1200°C. , when an accuracy of 5 or 10% suffices. This range embraces the temperatures involved in the heat treatment of ordinary steel and other metals and alloys.

Resistance Pyrometers.—These instruments were introduced by Siemens in 1871, and are still in use. The principal utilized is the increase in resistance to electricity shown by elementary metals when heated, which, in the case of platinum, has been proved by

Callendar to bear a definite relation to the rise in temperature. The working part consists of a coil of platinum wire, suitably shielded from furnace gases, and connected by platinum leads to one arm of a Wheatstone bridge, or to one branch of a differential galvanometer circuit. Compensation for the leads is effected by dividing the bridge at one end of the coil, so that the leads are in opposing arms (Siemens), or by dummy leads connected to the opposing arm of the bridge (Callendar). The reading consists in adjusting the bridge until a balance is obtained, when the resistance of the coil may be read, and the corresponding temperature deduced. For industrial use, indicators are provided in which the temperature is indicated on a dial when the bridge is adjusted to balance, so as to avoid calculation (Whipple, Siemens). Paul's indicator is a special form of ohmmeter, which requires no adjustment, and gives direct readings of temperature. Callendar's recorder is an automatic Wheatstone bridge, controlled by the galvanometer, a pen moving over the bridge wire giving an inked record. The Leeds-Northrup recorder achieves the same end by automatically balancing the pyrometer resistance against an opposing resistance in a differential galvanometer circuit. The resistance pyrometer is not now greatly used for industrial purposes, and is not suited for continuous use above 1000°C. , owing to an alteration in its indications due to the vaporizing of the platinum (Crookes). It is more costly and difficult to use than a thermo-electric pyrometer, but is capable of giving closer readings under steady conditions.

Total-Radiation Pyrometers.—The energy radiated by a "black body" or full radiator is proportional to the fourth power of the absolute temperature, and if the energy be measured the temperature can be deduced from the above relation. An enclosure at a constant temperature, such as a furnace, gives black-body radiations, and enables the laws of radiation to be applied to measuring temperatures without serious error. In most existing forms of total-radiation pyrometers, the rays from the heated enclosure are directed on to a blackened thermal junction, the temperature of which is raised in the proportion of the energy received. A galvanometer in circuit with the junction serves to indicate, by its deflections, the relative amounts of energy absorbed by the junction, and its scale may therefore be marked to read temperatures directly by applying the fourth-power law.

In the form due to Fery, the rays are focussed by means of a concave mirror on to a small metal disc to which the junction is attached, a different focus being required for different distances from the furnace. In Foster's fixed-focus instrument a concave mirror is placed at the closed end of a narrow tube, the radiations being admitted through a diaphragm at the open end, and reflected on to a thermocouple. So long as the lines joining the extremities of the mirror with the edges of the diaphragm fall, if produced, within the heated source, the reading will be the same at any distance. In the form due to Thuring, and made by Paul, the rays are made to enter a polished cone, at the apex of which a thermal junction is placed. Various other modifications have been used by different makers. Records may be taken by attaching the junction to any form of thermo-electric recorder, and employing a chart divided in terms of the fourth-power law.

Radiation pyrometers are used for temperatures ranging from 800° to 2000°C. , and are particularly valuable under circumstances which preclude the introduction of an instrument into the furnace, as in the case of rotary cement kilns.

Optical Pyrometers.—In the most reliable of these instruments the brightness of the red rays from the heated source is matched against a standard, and calibration effected by applying Wien's laws for the distribution of energy in the spectrum. The red rays from standard and source are obtained either by spectroscopic means, or by viewing through monochromatic red glass. In Wanner's pyrometer, and the Cambridge optical pyrometer, a polarizing device is used for matching the colours, the position of the analyser being made to indicate the temperature. In the Holborn-Kurlbaum type, made by Siemens, the filament of an electric lamp is placed in the focal plane of a telescope, and the image of the heated object brought into the same plane. The adjustment consists in increasing or decreasing the brightness of the lamp by means of a rheostat in its circuit, until the filament disappears into the background, the current taken by the lamp being then read and the temperature deduced from a law connecting this current with temperature. In Fery's optical pyrometer equality of tint of standard and source is obtained by means of absorbing wedges of glass which slide over each other. In all these cases experience is needed to secure an exact match. Optical pyrometers of the "extinction" type depend upon the complete absorption of the rays from the heated object, which may be effected by lowering a wedge of dark glass in front of the image as received in a telescope, as in the "Wedge" pyrometer, or by using a layer of densely coloured liquid, the depth of which may be adjusted, as in Heathcote's pyrometer. The temperature calibration in both these cases is obtained by taking readings at standard temperatures, and marking the instrument accordingly.

No satisfactory recording apparatus for optical pyrometers has yet been devised. Their chief advantages are the indefinitely high range—from 800°C. upward—and the possibility of obtaining readings from a considerable distance, and under conditions which would make it difficult to use any other type of pyrometer.

Miscellaneous Devices.—Amongst these may be mentioned: (1) Fusion pyrometers, which consist of pieces of materials of progressive melting-points, which are placed in the furnace, the temperature of which is represented by the melting-point of the highest in the series that undergoes fusion (Seger cones, Sentinel and Watkin's pyrometers); (2) Calorimetric or Water pyrometers, in which a piece of hot metal taken from the furnace is dropped into a known quantity of water, and the temperature deduced from the extent to which the water is heated; (3) Expansion pyrometers, based on the linear expansion of solids; and (4) the Clay-Contraction pyrometer of

Wedgwood. All these methods are at best approximate, and are not employed to the same extent as formerly, when accurate instruments were not available.

QUARITCH, BERNARD ALFRED (1871-1913), British bibliophile, son of Bernard Quaritch, the famous book-collector (see 22,711), was born Jan. 13 1871. He was educated at Charterhouse, and afterwards went to Leipzig and France. He joined his father's business in 1889, becoming its head in 1899. He played a very important part in the development of the firm, and purchased many rarities. He paid several visits to America, exhibiting there a large number of valuable books and MSS., and was a prominent purchaser at the Hoe sale (1911). He died at Brighton Aug. 27 1913.

QUEBEC (see 22,724*).—Through the addition of Ungava in 1912 the area of the Canadian province of Quebec was doubled, and it became the largest in the Dominion. From 227,500 sq. m. in 1801 it had increased to 351,873 sq. m., which with the addition of 354,061 sq. m. of Ungava (known as New Quebec) gives a total area of 706,834 sq. m. (about one-fifth of Canada), of which 690,865 sq. m. are land and 15,969 sq. m. water.

The pop. was 2,003,232 in 1911. It was estimated in 1921 at 2,350,000. About 98% are Canadian-born, and of these over 90% are of French descent.

The number of Indians in the province (including Ungava) was 13,366. The principal tribes are: Iroquois at Caughnawaga, Lake of Two Mountains, and St. Regis (the Indians of Lorette are also of Iroquoian stock); the Montagnais, who are of Algonquin stock, at Persimis, Mingan, Lake St. John, and Seven Is.; the Abenakis, also of Algonquin stock, at Becancour and St. Francis; the Micmacs, of Algonquin stock, at Maria and Restigouche; and the Malecites, Algonquin, at Viger.

Quebec, the capital of the province, had in 1917 a pop. of 103,000. Montreal (pop. in 1917, 700,000) is the largest city in Canada.

Hull (pop. 28,392), just across the Ottawa river from Ottawa, is a lumber centre with a rapidly growing population. Three bridges connect it with Ottawa. The water-power of the Chaudière Falls furnishes power for electric railways and for the lighting system as well as for saw mills, pulp and paper mills and match factories.

Sherbrooke (pop. 22,583) is a close rival of Hull in industrial importance. It is located in the Eastern Townships, and its cotton and woollen factories and machine shops are amongst the largest in Canada. St. Hyacinthe (pop. 16,540) and Valleyfield have also large manufacturing establishments. Three Rivers (pop. 25,000) and Joliette have large shipping interests.

The Government of the province consists of a lieutenant-governor, a Legislative Council of 24 members appointed by the lieutenant-governor in council, a Legislative Assembly of 81 members elected by the people, and an Executive Council of 11 members chosen from the Legislative Assembly and the Legislative Council. The province is represented in the Dominion Parliament by 65 members in the House of Commons, and 24 senators. Either French or English may be used in addressing either House of Parliament, but French is the language largely used. The Civil law is the old French code existing prior to the conquest in 1760. The Criminal law is the same as exists throughout the Dominion.

Education.—Very difficult problems presented themselves to the statesmen of Canada in connexion with education in the province of Quebec, for not only are 85% of the population Roman Catholics but 80% speak French as their mother tongue; and had it not been for the wise provision made as a condition precedent to confederation the Protestant minority of 15% would have found themselves in a very uncomfortable position. The superintendent of education for the whole province, who is a non-political officer, is assisted by a council divided into a Roman Catholic and Protestant committee, each with a secretary who is the chief administrative officer for both classes of schools respectively. These committees meet separately as a rule, though they may, and occasionally do, meet together as a council. Each committee supervises the expenditure of the proportion of public money allotted to it, and each has its own normal school, appoints its own teachers and exercises control by inspectors over its own schools under the general law. The

legislative grant for higher education is divided according to population, the Protestants receiving one-seventh; of the grant for normal schools the Protestants receive one-third, and the elementary school branch is divided according to population. This is supplemented by a local municipal taxation through trustees. In 1918 there were 6,103 elementary schools, with a teaching staff of 8,180 and a total enrolment of 247,531; the expenditure on education was \$14,481,494.

A leading feature of the educational system is that all the public schools are denominational. Instruction in religion and morals given in Protestant schools is based on reading from the Old Testament, the Gospels and the Acts, and the children commit to memory portions of the Gospels and Psalms, together with the Apostles' Creed, the Decalogue and the Lord's Prayer. The religious instruction in the Roman Catholic schools is substantially part of the educational system, the Roman Catholic schools being controlled by the clergy, the episcopate forming, *ex officio*, one-half of the Catholic section of the council.

The chief universities are McGill at Montreal, founded in 1820; Laval (R.C.), founded in 1852, the headquarters being in the city of Quebec; and the newly founded university of Montreal, which was formerly the Montreal branch of Laval. McGill University stands very high academically, and has an especially well-equipped department of applied science. Laval has a professional staff of 79, the university of Montreal 525, and McGill 322. The total numbers of students were in 1918 686, 5,460 and 2,444 respectively. Bishop's College, Lennoxville, is a small Anglican university in connexion with which is a school on the lines of an English public school. To McGill is affiliated the well-equipped agricultural college established at Ste. Anne de Bellevue by Sir William Macdonald, who is also noted for his liberal endowment of McGill University; and to Laval an agricultural school at Oka founded by the Trappist Fathers. There are numerous model and normal schools, the most important being that of Ste. Anne de Bellevue in connexion with Macdonald College.

Agriculture.—In recent years great progress has been made in agriculture, especially in dairying and live stock. The products of the soil are abundant, and large quantities of hay and oats are exported from Montreal and the city of Quebec; live stock, bacon, beef, eggs, butter, and especially cheese, to the value of millions of dollars yearly, are also shipped abroad. The field crops reach an annual value of \$271,600,000. Apples, plums and melons are produced in large quantities, together with many varieties of small fruits. Nearly \$7,000,000 is realized annually from the maple trees in sugar and syrup. In 1920 there were 813 butter and cheese factories in operation. More than 92,000,000 lb. of butter and cheese, worth over \$35,000,000, are produced each year. Fully two-thirds of the tobacco grown in the Dominion comes from Quebec. The live stock of the province was in 1920 valued at more than \$205,000,000, and the total annual value of the field crops, principally hay, oats, barley, and some wheat, at about \$305,000,000.

Forests and Lumber.—Quebec, though second to Ontario in the production of lumber, exceeds it in the value of its pulp and paper products. Of the enormous forest area but a small portion has been cut over, and since Quebec has been a pioneer in scientific methods of forest conservation, copying the method of old France, the timber resources promise to be maintained indefinitely. In the N. the predominating trees are pine, spruce, fir, and other coniferous varieties, while further S. appear maple, poplar, basswood, oak and elm trees and many other hardwoods. The value of the lumber cut in 1918 was \$20,916,604, of which spruce formed 66.3% of the output and white pine 13.1, the other commercial varieties in a smaller way being hemlock, balsam fir, birch and cedar. The capital invested in the lumbering industry amounted to \$57,201,820.

Fish and Fur.—The value of the annual catch of fish is estimated at \$3,000,000, the industry employing more than 3,000 men. Fish hatcheries have been established by the Dominion Government at several places for the purpose of stocking the lakes and rivers of the province. With considerable tidal waters along its coast Quebec may be regarded as one of the Maritime provinces. The principal fish are cod, lobsters, herring, salmon and mackerel. The mainland waters abound in trout, pickerel, whitefish, pike and sturgeon.

The forests, especially in the northern part, abound in game, both fur-bearing and otherwise. Nearly 200,000 sq. m. of territory in

* These figures indicate the volume and page number of the previous article

Quebec have been set apart by the Legislature for forest reserve and for the preservation of fish and game. Quebec is scarcely surpassed in Canada in its interest for sportsmen. In the Laurentides National Park, a district of 2,640 sq. m. N. of Quebec, caribou, partridge and trout are found in abundance. Bear and moose are also numerous.

Minerals.—Of the economic mineral product, cement alone yields \$3,000,000 annually. Molybdenite was mined extensively, during the World War, in the district of Quyon, Pontiac county, this mine becoming the largest producer in the world. Magnesite, found in the vicinity of Grenville, Argenteuil county, was also a valuable war-time mineral. The annual production of minerals in Quebec is valued at about \$23,000,000.

Manufactures.—Quebec ranks next to Ontario in the amount and value of its manufactures. There is limitless water-power almost everywhere, and at Shawinigan and Valleyfield power is being developed for commercial purposes. The chief manufactures are sugar, woollen and cotton goods, pulp and paper, tobacco and cigars, furs and hats, machinery, leather goods, boots and shoes, railway cars, rifles, musical instruments, cutlery and gunpowder. The annual value of the manufactured products of the province has reached \$920,000,000. The pulp mills in 1918 produced 288,952 tons valued at \$12,018,258, and the total product of all mills, paper and pulp, was valued at \$19,620,951. Paper of all kinds was manufactured to the extent of \$27,546,791, of which \$17,500,000 was newsprint. The total capital invested amounted to \$24,490,175, and 11,793 persons employed in the industry received \$11,546,596 in salaries and wages.

Communications.—The province is well provided with railways. The headquarters of the Canadian Pacific railway is at Montreal, and various lines of this railway connect Montreal with Toronto, Ottawa, Winnipeg, Vancouver, Quebec and St. John. The Canadian National railways connect Montreal with Halifax, passing across the St. Lawrence at the city of Quebec, and the line from Moncton, in New Brunswick, to Prince Rupert, in British Columbia, also crosses the St. Lawrence at the city of Quebec, and proceeds on its way through the northern part of the province. The National lines connect various local points, and by means of the old Grand Trunk system reach important centres in the United States, while there are a number of other railway companies, with lines running in various directions, especially in the extreme eastern section of the province.

Both Montreal and Quebec are connected by steamship during the summer months with all parts of the world. The St. Lawrence route, which by reason of its shortness is a favourite both for freight and passengers proceeding to Europe, has been rendered perfectly safe for navigation. During the summer season steamers ply on the rivers and inland waters, carrying a great deal of freight and taking care of the tourist trade.

(W. L. G.)*

QUEBEC (see 22.727), the oldest city in the Dominion of Canada, had a pop. of 78,710 in 1910 and 116,850 in 1920. Quebec had for some years prior to 1911 been displaced by Montreal in the shipping trade, but after 1911 the older port

steadily improved its commercial and industrial position. As a manufacturing centre Quebec has profited by the cheap electric power supplied from the Shawinigan and Montmorency Falls. The harbour has been improved, and the largest dry-dock in the world has been built at a cost to the Dominion Government of \$7,000,000. Important factors contributing to the increased commercial importance of Quebec were the successful completion of the famous Quebec bridge, and the building of the Grand Trunk Pacific railway from Prince Rupert on the west coast of Canada to Quebec on the east. The distance from Quebec to Winnipeg by this railway is 145 m. shorter than that from Montreal to Winnipeg by any other line. The Quebec bridge, connecting the north and south shores of the St. Lawrence river at Cap Rouge, 9 m. from the centre of the city, was completed in 1917 by the St. Lawrence Bridge Co. for the Dominion Government. This achievement marked the end of more than 10 years of effort, two accidents to portions of the huge structure having delayed the work in 1907 and again in 1917. The Quebec bridge is larger than the Forth bridge in Scotland, which was previously the world's largest bridge. Its total length is 3,239 ft., the cantilever span is 1,800 ft. long and the suspended span 640 ft. long. The weight of the suspended span is 5,510 tons. The completion of the bridge made possible the running of six railways simultaneously into Quebec from the south shore. Quebec has always been a base of supplies for a large region of mines, lumber camps and farms, but has gained further importance in this regard of late years owing to the rapid development of the water supplies of the province for purposes of electric power, particularly for the manufacture of wood pulp. The Lake Saint John district north of the city, a centre for pulp-milling, finds its outlet through Quebec. Buildings erected recently in Quebec include a large Government technical school, the erection and equipment of which cost \$150,000.

QUILLER-COUCH, SIR ARTHUR THOMAS (1863—), English man of letters (see 22.750), published subsequently to 1910 *The Vigil of Venus and other poems* and an anthology, *The Oxford Book of Victorian Verse* (1912), as well as books *On the Art of Writing* (1916), and *On the Art of Reading* (1920); a memoir of *Arthur John Butler* (1917); a volume of Shakespearean studies in 1918; *Hocken and Hunken, a new Tale of Troy* (1912); and various collections of short stories, including *Hicky-Nan, Reservist* (1915).

RACHMANINOFF, SERGEI VASILIEVICH (1873-), Russian composer and pianist, was born at Onega, in Russia, March 20 1873; his grandfather, an excellent pianist, had been a pupil of the Irish musician John Field. He began his studies under his mother, but at nine he became a pupil of Anna Ornadtzkaya. In 1882, however, the Rachmaninoff family removed to St. Petersburg, and Sergei entered the Conservatorium, where he remained till 1885, when, on the family again removing to Moscow, he joined the Conservatorium there, and was on terms of friendship with Scriabin, Siloti, Taneyeff and Arensky. When, in 1892, Rachmaninoff left the Conservatorium, he won the large gold medal for a one-act opera *Aleka* and followed it by many other works. About 1893 he composed a pianoforte suite, another for two pianos, a dozen songs, his first piano concerto, the symphonic picture *The Rock* and the elegiac trio on the death of Tchaikovsky. Next there followed his first symphony, produced by Glazounoff at St. Petersburg. In 1897-8 Rachmaninoff became conductor of Mamoutoff's private opera, a post he resigned after the season, and in 1899 he came to London to conduct a Royal Philharmonic concert. A second piano suite, another concerto and a violoncello sonata were quickly composed, and were followed by the one-act opera *The Miser Knight* (Moscow 1900, Boston 1910) and *Francesca da Rimini* (Moscow, same evening); during 1904-6 he directed the Moscow Opera, and from 1906 to 1908 he lived in Dresden as composer and pianist, visiting Paris in 1907. In 1909-10 he visited the United States for the first time, and then returned to Russia, where he wrote *The Island of Death*, the D minor piano Sonata, and the third and fourth piano concertos (1909 and 1917). In 1912 he produced *The Bells*, which was produced in Liverpool by Sir Henry J. Wood in 1921. Among his other compositions *Spring*, for chorus and orchestra, is particularly noteworthy, and his devotional music includes a wonderful setting of the Liturgy of St. Chrysostom (1910). In 1917 Rachmaninoff left Russia, and in 1918 he settled in New York.

RADIOACTIVITY (see 22.793*)—Among points of special interest that have arisen since the earlier article was written may be mentioned the preparation of metallic radium by Mme. Curie and Debierne by electrolysis of a radium salt with a mercury cathode. Radium resembles metallic barium, melts at about 700° C. and is rapidly attacked when exposed to the air.

The atomic weight of radium was found by Mme. Curie to be 226.45, using for the purpose about 0.4 gram of pure radium chloride. A recent careful redetermination by Hönigschmid with about one gram of radium gave a value 225.9 and is probably correct to 1 in 1,000. An International Radium Standard consisting of about 22 milligrams of pure radium chloride has been prepared by Mme. Curie, and is preserved in the Bureau International des Poids et Mesures at Sèvres, near Paris. Secondary radium standards have been issued to all governments who wished to purchase them. These have been calibrated by γ -ray methods both in Vienna and Paris and are supposed to be correct within 1 in 200. During the last few years the purchase and sale of radium have generally been conducted on certificates given in terms of this international standard.

The wide use of radium for therapeutic purposes, and its high cost—from £25 to £30 per milligram element—have led to close search for uranium deposits. The amount of radium in an old mineral is always proportional to its content of uranium in the ratio of 3.3 parts of radium by weight to 10 million parts of uranium. Consequently an old mineral containing 1,000 kgm. of uranium should contain 330 milligrams of pure radium. Initially several grams of radium were separated from the uraninite deposits in Joachimsthal, Bohemia, and some of the material, which was the property of the Austrian Government, was generously loaned to representative workers in radioactivity in England. A part of this radium is in the charge of the Radium

Institute of Vienna, which is specially devoted to radioactive investigations. The increasing demand for radium has led to the working of low-grade uranium ores on a large commercial scale. Much of the radium to-day is derived from the mineral carnotite, of which there are extensive deposits in Colorado and other parts of the United States. Although the carnotite contains only a few per cent of uranium and a correspondingly small quantity of radium, the separation of the latter is a profitable industry operating on a large scale. Large quantities of radium were employed by the Allies during the World War for night compasses, gun-sights, etc. The radium is mixed with phosphorescent zinc sulphide to form a paint which becomes continuously luminous, but, owing to the destruction of the zinc sulphide by the rays, this luminosity gradually decays.

Radium Emanation.—The atomic weight of the radium emanation is now known to be $226-4 = 222$, as was inferred earlier. This was confirmed by direct weighing with micro-balance by Ramsay and Gray.

The radium emanation has proved of great service not only in radioactive researches but also in therapeutic work. The radium salt is dissolved in an acid solution and the emanation is pumped off with the large quantity of hydrogen and oxygen liberated by the action of the radiations on water. After sparking the mixture, the emanation can be purified by condensation with liquid air. A very intense source of β and γ radiation can be obtained by introducing the purified emanation into fine capillary tubes. Such emanation needles have been widely used for therapeutic purposes, while the use of very thin-walled tubes provides a powerful line source of γ rays. The β and γ activity of such tubes rises to a maximum about four hours after introduction of the emanation and then decays with the period of the emanation, viz. 3.85 days. The quantity of emanation liberated from one gram of radium is called a *curie* and from one milligram a *millicurie*. The quantity of radium emanation in a tube can be accurately determined by comparison of its γ -ray activity with that of a radium standard, since the penetrating γ rays, both from the radium and the emanation in equilibrium, arise mainly from the same product radium C.

As regards other radioactive substances large quantities of mesothorium have been obtained as a by-product in the separation of thorium from monazite sands. This substance, which is half transformed in about 6.7 years, emits only β rays, but gives rise to radiothorium and subsequent products which emit α rays and penetrating β and γ rays. As a source of powerful β and γ radiation, this substance is very analogous to radium and can be obtained in about the same concentration. Since radium and mesothorium are isotopic elements, they are always separated together. Most commercial sources of thorium contain also uranium and radium, and consequently radium is always separated with the mesothorium and in relative amount depending upon the proportion of uranium to thorium in the mineral. Since mesothorium has a radioactive life short compared with radium, it commands a smaller price. The amount of mesothorium is standardized by comparison of its γ -ray effect with a radium standard.

Mme. Curie separated the polonium from several tons of pitchblende and obtained an exceedingly active preparation of a few milligrams, but was unable to obtain it in a pure state, although several of its spectrum lines were detected. It was hoped by this experiment to decide whether polonium was transformed directly into lead, but this was found difficult to establish owing to the presence of impurities with the very small quantity of polonium.

The three types of radiation, known as the α , β , γ rays, emitted by radioactive substances are analogous in many respects to the types of radiation observed when a discharge passes through a vacuum tube, but are of much more penetrating character. It may be noted here that for the electrons in a vacuum tube to obtain the velocity of the swift β rays from radium, a potential difference of at least two million volts would have to be applied. The very penetrating γ rays are identical in all respects with X rays of very short wavelength. Intense γ rays are only observed in substances which emit swift β particles, and apparently owe their origin to the passage of the swift β particle through the distribution of electrons surrounding the atomic nucleus. To produce X rays as penetrating as the γ rays, about two million volts would have to be cut on the discharge tube.

The α rays, shown in 1903 by Rutherford to consist of a stream of positively charged atoms projected with high velocity, are now known to consist of charged atoms of helium which are projected with velocities of about 10,000 m. per second. While the majority of products break up with the expulsion either of an α particle or a swift β particle, in a few cases no detectable radiation has been observed. Such products were at first called "rayless" products, but the sequence of

* These figures indicate the volume and page number of the previous article.

old minerals the transformations have been in progress for intervals measured by millions of years, the end-product should collect and be an invariable companion of the radioclement. Holtwood showed that lead is always present in old radioactive minerals and in amount to be expected from their uranium content and geologic age.

In recent years this problem has been definitely attacked in the light of the chemical generalization already given. It was clear from this that the end-products of uranium, thorium and actinium should all be isotopes of lead but with atomic weights 206, 208 and 206 respectively. In other words, uranium-lead if uncontaminated with ordinary lead should show a smaller atomic weight than ordinary lead (207), while thorium-lead should give a higher value. By the work of Richards, Soddy and Hönigschmid, these conclusions have been definitely confirmed. The lowest value for uranium-lead is 206, and the highest for thorium-lead 207.7.

Since any admixture with ordinary lead tends to give a value nearer 207, these results may be considered as a definite proof of the nature and atomic weight of the end-products. In minerals containing both uranium and thorium the atomic weight of the mixture of the isotopes will depend on the relative amounts of these two elements and their relative rates of transformation. In unaltered minerals the determination of the amount of lead coupled with its average atomic weight allows us to determine the amount of uranium-lead even if some ordinary lead be present. In this way it should be possible to make a reliable estimate of the age of selected minerals and thus indirectly the age of the geologic strata. The amount of helium in the mineral gives a minimum estimate of its age, for, except in the most compact minerals, some of the helium must undoubtedly escape.

Nature and Properties of the α Rays (re-stated).—Although the α rays from active substances are of small penetrating power compared with the β or γ rays, they are responsible for most of the energy evolved by radioactive substances and contribute most of the ionization. Rutherford showed in 1903 that the α rays were deflected in a powerful magnetic and electric field and consisted of positively charged particles projected with high velocity. From the first it seemed probable that the α particle was an atom of helium and this was subsequently confirmed in a number of ways. The value of e/m —the ratio of the charge on the particle to its mass—and the velocity can be determined from observations on the deflection of the pencil of rays by a magnetic field and electric fields. In this way Rutherford and Robinson showed that the α particle, whether from the radium emanation, radium A or C, gave a value of $e/m = 4820$ c.m. units, while the electrochemical value of $e/m = 4826$, assuming that the mass of the helium atom is 4.00 and that it carries two unit positive charges. The magnitude of the charge carried by each particle was measured by Regener and Rutherford and Geiger and found to be twice that carried by the electron. The velocity of the α particles expelled from radium C (of range 7.06 cms.) was found to be 1.92×10^9 cm. per second, or about $1/18$ the velocity of light. From this result the velocity of expulsion of all α particles can be calculated from the relation found by Geiger, that $V^2 = KR$ where V is the velocity of the particle and R its range in air. The evidence indicates that the α particles from active products are in all cases atoms of helium. The α particles from a given product are all emitted with constant velocity which is characteristic for that product. We have already mentioned that the velocity of expulsion appears to be connected with the period of transformation of the element. The laws of absorption of the α particle were first worked out by Bragg and Kleeman. On account of their great energy of motion, the α particle travels in nearly a straight line through the gas, producing intense ionization along its track. The effects produced by the α particle, whether measured by ionization, phosphorescence or photographic action, vanish suddenly after the α particle has traversed a definite amount of matter. This definiteness of the end of the range of the α particle of given velocity is remarkable. The range of the α particle is usually expressed in terms of cms. of air traversed at 15° C. and 760 mm. pressure.

On account of its great energy of motion the effect due to a single α particle can be detected in a variety of ways. Sir William Crookes

first noted that the α rays produce scintillations when they fall on a screen of phosphorescent zinc sulphide. It is now known that each of these scintillations is due to the impact of a single α particle. The number of scintillations can be counted with the aid of a suitable microscope, and this method has proved of great utility in many investigations. Scintillations due to α rays are observed in certain diamonds, but they are usually not so bright as in zinc sulphide. Kinoshita has shown that a single α particle produces a detectable effect on a photographic plate. When the α rays fall on a plate nearly horizontally the track of the α particle is clearly visible under a high-power microscope. By the expansion method developed by C. T. R. Wilson, the track of the α particle through the gas is made visible by the condensation of the water on each of the ions produced. In a similar way the track of a β particle can be easily shown. The photographs of these trails bring out in a striking and concrete way not only the individual existence of α and β particles, but the main effects produced in their passage through matter.

Properties of β and γ Rays (re-stated).—We have seen that the β particles, which are emitted by a number of radioactive products, consist of swift negative electrons spontaneously liberated during the transformation of active matter. The velocity of expulsion and the penetrating power of β rays vary widely for different products. For example, the rays from radium B are much more easily absorbed by matter than the swift β rays from radium C. Moseley showed that in the case of these two products each disintegrating atom gave rise on the average to one β particle.

There is undoubtedly a close connexion between β and γ rays, and swift β rays are usually accompanied by penetrating γ rays. For example, radium C, which emits very swift β rays, some of which reach a velocity more than 0.98 of the velocity of light, gives rise to the most penetrating γ rays observed in the uranium-radium series. There is one very notable exception, viz. radium E, which emits swift β particles but weak γ rays. Gray has shown that β rays in passing through matter give rise to γ rays, and that these in some cases correspond to the characteristic X radiations observed by Barkla. The absorption of the γ rays has been determined by the electrical method. Radium B has been found to emit several groups of γ rays which differ widely in penetrating power. The greater part of the rays from radium C consist of penetrating γ rays which are exponentially absorbed by matter. The ionization in an electroscope falls off according to the equation $I/I_0 = e^{-\mu d}$ where d is the thickness of matter traversed and μ the coefficient of absorption. When lead is used as an absorbing material the value of $\mu = 0.5$ for the most penetrating γ rays from radium C. The absorption coefficient for different kinds of matter is roughly proportional to the density, indicating that the absorption depends only on the mass of matter traversed.

The general evidence indicates that the γ rays consist of types of characteristic radiations which are excited by the passage of the β rays through the electronic system of the atom, but the γ rays from radium C are far more penetrating than any type of characteristic radiation observed in X rays generated in a vacuum tube.

Rutherford and Andrade have determined the spectrum of the γ rays from radium B and C by reflection from rock-salt. The most intense lines due to radium B are identical in wave-length with the X-ray spectrum of lead. This is to be expected, since radium B is an isotope of lead. The lines due to the "K" characteristic radiation are also observed. General considerations, however, indicate that the wave-length of the most penetrating γ rays is much too short to resolve or detect by the crystal method. In order to excite such rays in an X-ray tube potential differences of the order of two million volts will be necessary.

When the γ rays from a product like radium B or radium C are bent by a magnetic field and fall on a photographic plate, a kind of magnetic spectrum is obtained. Superimposed on the continuous spectrum due to particles of all velocities (between certain limits) certain sharp lines are observed, each of which represents a definite group of β rays which are emitted at the same speed. The velocity corresponding to each line in the spectrum has been determined for a number of β -ray products by Hahn and Miss Meitner. The magnetic spectrum of radium B and radium C was examined in detail by Rutherford and Robinson and more than 50 lines were observed, representing β particles projected over a wide range of velocity. The appearance of these lines in the spectrum appears to be connected with the emission of γ rays and is believed to be due to the conversion of the energy of the γ ray of definite frequency into the energy of an electron according to the quantum relation. When a thin layer of absorbing material is placed over the source, the primary β rays diminish in velocity and the lines become broad and diffuse. At the same time, however, new groups of β rays are formed by the conversion of γ rays into β rays in passing through the absorbing material, and these give well-marked bands on the photographic plate, occupying very nearly the same position as those due to the primary β rays before absorption. Results of this kind have an important bearing on the general problem of radiation, and give us indications of the facts to be accounted for in dealing with the conversion of swift β rays into γ rays of high frequency, and vice versa.

Production of Helium.—It was stated in the earlier article that, since the particle is an atom of helium, all radioactive matter which emits α particles must produce helium. This has been found to be the case for every α -ray product that has been examined. The rate of production of helium by radium in equilibrium has been measured with accuracy by Dewar, Boltwood and Rutherford. In terms of the International Radium Standard, the rate of production of helium by one gram of radium in equilibrium with its three α -ray products has been found to be 164 cub. mm. per year. This value is in excellent accord with that calculated from the rate of emission of α particles, viz. 163 cub. millimetres. The rate of production of helium by the radium emanation, ionium and polonium has been found by Boltwood to be in fair agreement with calculation. Soddy has observed the production of helium by purified uranium, while Strutt showed that the rate of production of helium in uranium and thorium minerals accorded with calculation.

Strutt has made a systematic examination of the amount of helium present in many minerals and rocks which contain minute quantities of radium and has utilized the results to estimate the age of the geological deposits. On account of the tendency of the helium to escape from minerals in the course of geologic ages, this method gives only a minimum estimate of the age of the mineral, except in the case of very dense and compact specimens. The measurement of the lead content should ultimately prove a more reliable method of estimating the age.

Heat Emission of Radioactive Matter.—As was stated earlier, there is no doubt that the evolution of heat by radium and other radioactive matter is mainly a secondary phenomenon, resulting mainly from the energy of the absorbed radiation. Since the particles have a large kinetic energy and are easily absorbed by matter, all of these particles are stopped by the radium itself or by the envelope surrounding it and their energy of motion is transformed into heat. The evolution of heat from any type of radioactive matter is thus proportional to the energy of the expelled α particles, together with the energy of the β and γ rays absorbed in the envelope. The energy supplied by the recoil of the radioactive atom after the expulsion of an α particle is about 2% of the energy of the α particle.

These conclusions have been confirmed by the measurements of Rutherford and Robinson, who found that each of the α -ray products gave a heating effect proportional to the energy of the α particle and absorbed β and γ rays. The emanation and its products when removed from radium were responsible for three-quarters of the heating effect of radium in equilibrium. The heating effect of the radium emanation, radium A and radium C decayed at the same rate as their activity. From their measurements they found that the total heating effect of radium in equilibrium surrounded by sufficient material to absorb the α rays was 134.7 gram-calories per hour per gram. Of this, 123.6 gram-calories were due to the α particles, 4.7 to the β rays and 6.4 to the γ rays. The energy of the β and γ rays comes from radium B and radium C, but on account of their great penetrating power it is difficult to measure the β energy with accuracy. The results, however, show that the energy of the γ rays is even greater than that of the β rays, and the two together are equal to about 28% of the energy of the α particles from radium C.

Measurements have been made of the heating effect of radium, uranium and thorium and of uranium and thorium minerals. In each case the evolution of heat is of about the magnitude to be expected from the energy of the radiations.

Radioactivity of Ordinary Matter.—Apart from the well-known radioactive elements of high atomic weight, only two other elements have been shown to exhibit the property of radioactivity to a detectable degree, viz. potassium and rubidium. Campbell showed that these elements emit only β rays and in amount small compared with uranium. This property appears to be atomic, but no evidence has been obtained of any subsequent changes. If the β particle comes from the nucleus of the atom, potassium should be transformed into an isotope of calcium, and rubidium into an isotope of strontium.

Radium and thorium have been found to be distributed, but in very minute amount, in the surface rocks and soil of the earth. The emanation from the soil diffuses into the atmosphere and causes a small ionization which can be readily measured. A penetrating γ radiation, no doubt due to the presence of radium

and thorium in the earth's crust, has been observed near the earth's surface, but becomes very small over a lake or the sea.

Soddy, *Chemistry of the Radioelements*, parts I. and II. (1914-5); see also under "Radioactivity" in annual *Reports of the Chemical Society*. (E. RU.)

RADIOTHERAPY.—Since 1910 there have been notable developments, extending the practice of X-ray treatment (see 28.887) into the wider field now included in radiotherapy, a term which had not then come into general use. Strictly speaking, under this term should be included treatment by all kinds of rays; thus treatment by heat, by sun's rays, by ultra-violet rays, by X-rays and by the rays of radio-active substances, all come under the etymological term of radiotherapy. In practice, however, it is restricted to the application of ultra-violet rays, X-rays and radium rays. Amongst radiologists, the term has undergone an even sharper definition, so that radiotherapy is applied by them to treatment with X-rays alone, the terms radiumtherapy (or, in France *curietherapy*, in honour of the discoverer of radium) being applied to treatment with the rays of radium and other radio-active substances. Treatment by means of high frequency currents and diathermy are included rather under the term electrotherapy.

Ultra-violet Rays.—These rays to a large extent are the essential feature of those forms of medical treatment which depend upon exposure to sunlight (heliotherapy). Probably this is not the whole story. Even though heat rays may also play some part, experience of the treatment of wounds by sunlight in France during the World War indicated that a degree of benefit arises from exposure to sunlight which cannot be entirely attributable to warmth and ultra-violet rays. On the other hand, in the Finnsen light treatment of lupus and in the treatment of tuberculosis at high altitudes, ultra-violet rays probably play a predominant part. It is uncertain how these rays act; they penetrate but a fraction of a millimetre into the epithelium and yet the fact that in tropical countries where sunlight is great, the white races show a proverbial irritability which does not characterize the pigmented native races, suggests that in the one, effects are produced by the ultra-violet rays which the pigment of the other is able to eliminate. Certain it is that under ultra-violet light, persons vary in the appearances they present, those who freckle or tan easily when exposed to sunlight showing the potential freckles or bronzing of their skin by dark marks which are absent from the skins of those who do not freckle or tan easily. In this connexion, it is noteworthy that those tuberculous persons are said to derive greater benefit from a sojourn at high altitudes who normally tan easily under sunlight, than those who do not. The rays are bactericidal, but whether part of their action lies in this direction, is unknown.

X-rays.—The X-rays which were discovered by Röntgen in 1895 are employed in medicine in two ways, firstly, as an aid to diagnosis when they form those branches of the subject known as radiology and radiography, and secondly, for the actual treatment of conditions when diagnosed. Thus by means of radioscopic or radiographic examination it may be found that there is a tumour in the chest, and as a result of that diagnosis it may be decided to institute treatment (radiotherapy) by means of X-rays or radium rays or the two combined.

X-radiation has the advantage that considerable doses can be employed. It has the disadvantage that the X-rays are frequently not of sufficiently penetrating power to serve for the treatment of tumours deep within the body. Three varieties of X-rays are used, the difference consisting in variations in wave lengths and in penetrating power. These varieties are known clinically as "soft," "medium" and "hard" X-rays, the soft rays being those of longer wave length and less penetrating power, and the hard rays being those of shorter wave length and greater penetrating power. The softest X-rays are not used clinically; those employed in the treatment of ringworm for example are "medium soft" since it is necessary for penetration to reach as deeply as the hair follicles. Medium

hard and hard X-rays are used where a layer or mass of tissue some little distance beneath the surface is to be treated.

For the better treatment of new growths removed some distance from the surface of the body, there is a tendency at the present time (1921) to increase the hardness of the rays to the utmost extent with the object of producing a radiation that approximates in some degree to the gamma rays of radium in penetrating power. Chief amongst the new growths that are the subject of this "deep therapy" with intensely penetrating X-rays are uterine fibroids. The production of soft to medium X-rays requires an apparatus capable of generating about 100,000 volts, for deep therapy a voltage of about 200,000 is necessary and the aim of radiologists is to get a still higher voltage. The method employed is essentially use of a series of transformers.

It is unnecessary here to enter into a detailed examination of the methods whereby X-ray dosage is determined, but it is obvious that estimation of the dose is one of the most important points in connexion with radiotherapy. In the case of radium, the matter is relatively simple, for the output of rays from the radium is constant, but in the case of the X-ray bulb, quite apart from variations in the primary current, the conditions of the bulb vary within wide limits, and the output of the bulb in X-rays varies accordingly. An important advance has been made in recent years by the introduction of the Coolidge tube in which by means of a different working principle the output of X-rays can be kept fairly steady. Under all circumstances, the output of an X-ray bulb is heterogeneous, the bundle of rays emitted is partly penetrating, partly soft, and in order to produce a more or less homogeneous bundle of rays for purposes of treatment, it is necessary to eliminate the softer varieties by means of filters. These filters are of different kinds but the chief are aluminium, zinc, copper and lead. For absorption of the specific secondary radiations produced when gamma or X-rays impinge upon metals, such substances as rubber, gauze, cardboard are used.

When a more or less homogeneous beam has been produced, it is necessary to calculate the dose employed in any given case for comparison with other cases. Various means have been adopted to this end, of which the commonest is the Sabouraud's pastille which consists of barium platinum cyanide and changes colour from green to yellow under a certain dosage of the rays. It was thought at first that this colorimetric test would be generally applicable, but it was soon found that the change is not brought out by X-rays of all degrees of penetration and is fallacious as a guide to gamma radiation of radium. It is now largely employed as a test of dosage during the X-ray treatment of ringworm and other skin diseases, but it is recognized that it must only be employed with caution, with rays of medium hardness, and for superficial conditions. Another form of test is electrical (ionto quantimeter) in which the rate of discharge of a charged gold leaf forms a measure of the output of X-rays. Another method depends upon the chemical reduction of iodine from iodoform in a chloroform solution and is probably the most scientifically accurate of all the methods which have been devised. Yet other methods depend upon the correlation between the effects produced by X-rays on the one hand and the gamma rays of radium on the other. Here the production of identical degrees of fluorescence on the fluorescent screen or of silver deposit on the photographic plate or of biological effects on the animal cell has been aimed at in standardization.

So far as treatment is concerned, it is obvious that a biological test is the most satisfactory. The one commonly used is known as the "erythema dose," meaning thereby that dose of X-rays which leads to a reddening of the skin a few days after application and subsequently to slight bronzing, without blistering or other damage. On the other hand there is no doubt that the various cells of the body do not react to radiations in the same degree and partly on this account and partly because of the operation of the law of inverse squares, it is obvious that the skin over a tissue being irradiated may itself receive an injurious dose while the tissue in question is receiving the correct dose. Hence when a tissue some distance beneath the surface is under

treatment it becomes necessary to irradiate it through different portals, so that each area of skin shall receive less than the erythema dose, although the tissue in question gets the full amount that the radiologist wishes to give it; this method of cross fire is largely employed.

Radio-active Substances.—Treatment by means of radio-active substances largely resolves itself into treatment by means of the beta and the gamma rays of radium or occasionally mesothorium. Just as X-rays vary in degree of penetration, so do the rays of radium. The so-called alpha rays are little penetrating, being stopped by about 3½ cm. of air. The beta rays, which are particulate negative electrons, are more penetrating but their penetrating power varies over a wide field, some of the softest being as easily absorbed as alpha rays, some of the hardest approximating to the soft gamma rays in penetrating power. Gamma rays are aether vibrations and they, too, vary in degree of penetrating power. Their wave length is the shortest of any form of vibration known, and the most penetrating gamma rays can be detected through several inches of lead.

The alpha rays are but little used, the only methods of employment being in the way of radium emanation dissolved in saline solution, or of needles upon which "active deposit" from radium emanation has been collected. In either case the emanation water or the active deposit needles must be introduced into the system—whether intravenously or into the solid tissues—otherwise the alpha rays would have no power to act. In either case, too, they act along with the beta and gamma rays produced by the active deposit.

Beta radiation is always used in conjunction with gamma radiation, but inasmuch as the ionizing power of the beta ray is about 50 times as great as that of the gamma ray, it follows that when beta radiation is being employed, the gamma radiation may probably be ignored. Beta radiation is used for merely superficial conditions and the radium salt which supplies it is spread over a flat or curved applicator and is covered with a thin layer of varnish, mica or aluminium or is placed in a thin glass tube; the beta rays which traverse thin solid filters act upon the tissue in the neighbourhood of which the radium is placed. Instead of a radium salt one of its products, viz. radium emanation is often employed clinically. No essential difference is introduced by the use of this emanation excepting that its intensity undergoes a progressive diminution with time since it falls to half value in 3.85 days. Early rodent cancer, certain conditions of the eyelids, some cutaneous non-malignant tumours and birth-marks, are treated successfully in this way.

Gamma radiations are used where deep penetration is required, but the law of inverse squares approximately holds good in their case also, a matter of fundamental importance in treatment. The substances used as filters when radio-active materials are employed in treatment are not quite the same as those used along with X-rays. Since one of the main objects in employing radium is to utilize the highly penetrating gamma rays, the filters employed are generally of the higher atomic weights, silver, brass, gold, lead, platinum, and there is some reason for believing that the more highly penetrating the rays, (i.e. the denser the filter through which they have passed) the less is undesirable damage suffered by the tissues.

Mode of Action of Radiations.—The method by which X-rays and radium rays produce their effects are not thoroughly understood, but it is certain that dosage must vary according to the type of cell which it is desired to influence. Thus the vulnerability of skin is not the same in different individuals nor even in different regions in the same individual; the vulnerability of the squamous cell is not the same as that of the columnar cell; the vulnerability of renal cells differs in the convoluted tubules and in the conducting tubules. Even in the fur of animals it is possible to recognize a differentiation, for a certain amount of X-radiation will lead to a destruction of the pigment forming cells in the hair of a black rat, while a little more radiation will affect the cells themselves. In the former case there is no epilation but the hair comes white instead of black, in the latter the hair falls out and baldness results.

If the question be carried still further back and the behaviour of the cells themselves under radiation be considered, it has been found that the rays may act principally, though not exclusively, upon the nucleus or upon the cytoplasm or upon the cell membrane or upon any paraplasmic material within the cell. The greater amount of work in this direction has been carried out with radium but there is little doubt that the effects of X-rays are similar. In part, changes are produced owing to the fact that the radiations break down complex chemical substances into simpler constituents. In this way, the osmotic tension of the cell or nucleus affected is raised and a dropsical condition results which can often be recognized microscopically. Other forms of degenerative change produced are fatty and mucoid. Thus radiation, if in great doses, will lead to fatty change in voluntary muscle of man and most animals or in renal cells of the cat. Under large doses of radium, mucoid changes are excessively common in all parts which normally produce mucus, but in addition, there is a great tendency for cells which ordinarily do not form mucus to undergo mucoid degeneration. Sometimes the cytoplasm of the cells disappears, though not obviously by way of either of these changes, with the result that the nucleus lies naked in the middle of the cell and separated from the cell membrane by a considerable distance. So far as the nucleus is concerned, changes produced by radiations may be intense. In cells such as those of testicle or intestine which are often found in mitotic division, mitosis is arrested or abolished. In other nuclei there may be evidence of vacuolation or the nucleus may be converted into a mere empty sac, or the nuclear membrane may disappear, or the entire nucleus may be represented by a few points of stained material or, finally, the nucleus may disappear altogether.

Thus in one or other way, changes are produced as the result of irradiation in the tissues upon which those rays impinge and the effects produced will depend upon (1) the type of cells affected, (2) the quantity of rays employed, (3) the length of time those rays have acted.

It must be remembered that the biological cell usually acts in one or other of two opposite directions when exposed to a physical agent according to the intensity with which the agent acts. Thus we distinguish between a stimulating or beneficial effect and an irritative or injurious effect. There is reason to believe that both of these may follow upon irradiation. In the case of malignant new growths, there is no doubt that death and destruction of the neoplastic cells occur where the rays act in all their intensity, but there is equally no doubt that because of the law of inverse squares and the specific absorption by the tissues a point is reached at which the injurious effect on the malignant cells which we desire passes into a stimulant effect which we may have reason to deplore. If this stimulus act on young and actively growing malignant cells at the periphery of the growth our irradiation will do more harm than good to the patient. There can be little doubt that in the early days of radiotherapy, some cases of malignant disease ran a more rapid course as the result of the irradiation treatment than otherwise they would have done. For this reason, the essential point of their treatment by means of radium consists in an endeavour to deal with the peripheral neoplastic cells.

On the other hand, changes may be produced in cells which we are unable to recognize microscopically. Recently the treatment of exophthalmic goitre has been largely and for the most part, successfully, carried out by irradiation and yet if the thyroid body be examined from animals exposed for many hours to the gamma radiations of radium bromide, it may be doubtful whether histological changes can be detected. Similarly, intense gamma radiation of the male frog produces no testicular changes that can be detected with certainty, and yet far less radiation produces marked changes in the tadpoles derived from normal ova fertilized by such radiated spermatozoa.

It follows from what has been said above, that radiotherapy is not without its special dangers. Amongst the disadvantages to which the irradiations may give rise, too extensive destruction of tissue on the one hand or stimulation of new growth on

the other are relatively obvious but the dangers are more insidious. Recent work has shown that long continued exposure to minute doses of radiation (in addition to the well-known occasional production of skin cancer) leads to blood changes which in course of time become a pronounced menace to life. Not only are red and white blood cells destroyed, but the rays appear to exert a deleterious effect upon the blood-forming tissues with the result that an aplastic anemia becomes established. Obviously, the protection of the personnel in hospitals and similar institutions where X-rays and radium are used becomes a matter of great importance.

It is probable that X-rays and radium will always continue to be employed side by side owing to the special advantage which each form of radiation possesses, and in some cases it is certain that the best results are obtained in combination.

It will have appeared from what has been said above that radiotherapy is largely—though by no means exclusively—concerned with the treatment of new growths. Irradiation by one or other method is used in cases of uterine fibroid and in cases of inoperable cancer, sometimes with astonishingly good results. It is also used in conjunction with operation for cancer with the object of warding off recurrences. Sometimes cancers, inoperable when they first come under observation, are rendered operable by treatment with radium. And, frequently, when surgery has done all that is possible a considerable degree of relief is given by irradiation.

In addition to their use in the treatment of new growths, X-rays and radium have been tried in most of the chronic forms of disease. When surgery or medicine fails to relieve a case, it is usual to try irradiation. Sometimes the results are surprisingly beneficial, but the limits of utility of the rays still need to be determined. (W. S. L-B.)

RAEMAKERS, LOUIS (1869—), Dutch cartoonist, was born at Roermond, Holland, April 6 1869. He received his education in art at various schools, and finally at Amsterdam, where he obtained several prizes. He subsequently became director of an art school at Wageningen, in Gelderland. About 1908 he started drawing political cartoons, but it was not until the outbreak of war in 1914 that his work attained world-wide reputation, by his anti-German cartoons, illustrative of the devastation of Belgium and Northern France. Many special exhibitions of his war cartoons were held, and his work had a great effect as propaganda. Several volumes of his work have been published: *The Great War in 1916*; *The Great War in 1917*; *Devant l'Histoire* (1918); *Cartoon History of the War* (1919).

RAILWAYS (see 22.810; also **LIGHT RAILWAYS, MILITARY**).—UNITED KINGDOM.—In 1910 British railways had reached a high standard of completeness and development, and, although a number of new lines were subsequently brought into use, two only are of primary importance in regard to through main-line traffic. One of these is the first section of the Enfield-Stevenage line of the Great Northern railway, opened for traffic as far as Cuffley on April 4 1910. On the same date the Ashenden-Aynho line of the Great Western railway was brought into use for goods traffic. The former was part of a new line designed to afford an alternative route into London avoiding duplication of the Welwyn Viaduct and, by adopting a new route, opening up a new district near London for suburban development. From 1916 onwards the northern portion was laid with a single line and used for goods traffic, and towards the end of 1920 a second track was laid. In June 1921 this section had not yet been opened for passenger traffic, but was already being largely used for goods and mineral trains. The Ashenden-Aynho line was, however, on July 1 1910, brought into regular use as part of a shortened main route between London and Birmingham, and a two-hourly schedule then came into force for the principal Great Western expresses.

Among other important new lines brought into use the following may be mentioned: June 1 1910, Filton Junction and Avonmouth Docks, and the Camerton and Limply Stoke lines, G.W.R.; Armagh, Keady & Castleblaney railway, worked by G.N.R. (I.), completed December 1 1910; April 13 1911, Shropshire & Montgomeryshire light railway; May 12 1911, Lampeter and Aberystwyth

line, G.W.R.; May 1 1912, Goole and Selby line, N.E.R.; June 3 1912, Dearne Valley railway (worked by L. & Y.R.); June 16 1913, Mansfield railway opened for goods traffic, and on April 2 1917 for passenger traffic (worked by G.C.R.); and July 1 1913, Kirkstead and Little Steeping Line, G.N.R. On July 1 1912 the London & North-Western railway brought into use a part of the "Watford new lines," and the branch to Croxley Green, the remainder being opened on Feb. 17 1913. On June 2 1913 the Great Western railway opened part of the remarkable series of lines designed to improve railway communication in South Wales and referred to generally as the Swansea District lines. Other sections were added at various later dates. On Sept. 26 1915 the North British railway brought into use a series of new lines in the Edinburgh district, designed mainly to facilitate mineral traffic working, known as the New Lothian lines. On May 22 1916 the Great Central railway opened the Keadby deviation line, including a new bridge over the Trent with a Scherzer rolling-lift bridge of 200 ft. span. In July 1915 a section of the old Ravenclaw and Eakdale railway in Cumberland was reopened on the 15-inch gauge, using locomotives of model or "exhibition" types, but catering to public passenger and goods traffic. Extensive reconstruction works at Waterloo, L. & S.W.R., were nearing completion in 1921.

Electric Railway Extensions and New Lines.—On July 27 1912 the Central London railway was extended to Liverpool Street. On December 1 1913 the "Bakerloo" section of the London Electric railway was extended to Paddington, and on February 11 1915 to Queen's Park, there connecting with the L. & N.W.R. On April 6 1914 the loop under the river at Charing Cross on the "Hampstead" section of the London Electric railway was brought into use. On May 31 1915 the four-track section, from Finchley Road to Harrow, of the Metropolitan railway was completed over Kilburn Viaduct. On Aug. 3 1920 the Ealing and Shepherd's Bush railway, connecting the Central London railway at Wood Lane with the G.W.R. at Ealing Broadway, was completed and opened for traffic.

Railway Electrification (see also ELECTRICAL ENGINEERING).—Equipment of existing railways for electric working has been considerably extended. On May 12 1911 the L.B. & S.C.R. commenced to work electric trains between Victoria and the Crystal Palace. On March 1 1912 the London Bridge routes via Tulse Hill were added, the complete electric service becoming operative on June 1 1912. Since that date equipment of various other routes has been in hand but owing to interruption of the war no further sections are yet electrically operated. On the London & South-Western railway electric traction was inaugurated between Waterloo and Wimbledon, via East Putney, on Oct. 25 1915; on the Kingston "Roundabout" route Jan. 30 1916; on the Hounslow loop March 12 1916; to Hampton Court June 15 1916; and to Claygate Nov. 20 1916. Electric working on the North London and L. & N.W. railways was commenced between Willesden Junction and Earl's Court on May 1 1914, and between Broad Street and Richmond and Kew Bridge on Oct. 1 1916. On May 10 1915 the London Electric railway commenced to work through to Willesden Junction via Queen's Park, and from April 18 1917 this service was continued to Watford over the "Watford New Lines," though it was not until 1920 that the L. & N.W.R. was able to take its share in the working of this service, as the specially constructed joint rolling stock began to be delivered after the war from the makers. During 1919 L. & N.W.R. electric trains began to work from Broad Street to Watford via Hampstead Heath. Work was in 1921 well advanced upon the new "tube" tunnel under Primrose Hill and the entire reconstruction of L. & N.W.R. lines at Chalk Farm to enable "flying" or "burrowing" connexions to be made between the Euston and Broad Street routes and between the three sets of running lines, but electric operation could not be inaugurated via Chalk Farm and from Euston until this was sufficiently completed. On March 31 1912 Metropolitan railway electric trains commenced to work over the East London railway between Shoreditch and the two New Cross stations, with through trains, via Aldgate East, to and from Hammersmith. Principal developments in regard to electric traction in the provinces are the electrification in 1916 of the Newport-Shildon section of the North-Eastern railway to enable heavy mineral traffic to be operated by electric instead of steam locomotives, and of the L. & Y.R. route from Manchester (Victoria) to Bury, via Prestwich, in Feb. 1916, following the experimental high-tension electrification between Bury and Holcombe Brook which had been used from July 1913.

Mention may also be made of the installation in 1911 of escalators at Earl's Court, connecting the "Piccadilly" section of the London Electric railway with the Metropolitan District station above. Escalators were also provided at Liverpool Street on the opening of the Central London railway extension in July 1912, since which date these have been systematically adopted at all new tube railway stations. They have also been introduced at several existing stations, as at Oxford Circus, London Electric railway, and on the L. & S.W.R. at Waterloo to connect the Waterloo and City station with the terminus above.

Dock Improvements.—Principal developments in regard to dock and similar facilities affecting railways are the opening of Immingham Dock, G.C.R. (by the King and Queen) on July 22 1912; of the new Methil Docks, N.B.R., on Jan. 22 1913; of the King George Dock at Hull, H. & B. and N.E. railways (by the King and Queen)

on June 26 1914; and the opening of a new lock entrance, designed to enable the largest vessels to enter at all states of the tide, at Newport, Alexandra Docks & Railway, on July 14 1914.

New Locomotive Works.—During 1910 and 1911 the new locomotive works at Eastleigh of the L. & S.W.R. were brought into use, and the old works at Nine Elms dismantled and the area thus cleared handed over to the Goods Department. The Great Eastern railway added several new workshops to the rolling-stock plant at Stratford in 1914-6.

Signalling.—Automatic and power signalling had already become well established in 1910, but only a limited amount of further development can be recorded. In Jan. 1911 two-position upper-quadrant electric signals were introduced on the Metropolitan railway, and have since been adopted where semaphores are retained on the "Underground" sections. On the Keadby deviation line of the G.C.R., already mentioned, three-position upper-quadrant signals have been in use since May 1916, while the Ealing & Shepherd's Bush railway is the first line in the United Kingdom to be opened with all signals of this type. In Jan. 1920 a complete power signalling installation on three-position upper-quadrant principles was brought into use at Victoria, S.E. & C.R.

Express-Train Running.—During the years 1910-4 express passenger-train facilities reached their highest level, and the time-tables arranged for the summer of 1914 showed the following numbers of non-stop runs of 100 m. or more: *Caledonian railway* 10 runs, the three longest being between Carlisle and Perth, 150½ m.; *Great Eastern railway* 7 runs, the two longest being of 131 m. between Liverpool Street and North Walsham; *Great Northern railway* 29 runs, the longest being from Wakefield to King's Cross, 175½ m.; *Great Central railway* 6 runs, the longest being from London to Sheffield, 164½ m.; *Great Western railway* 40 runs, the longest from Paddington to Plymouth (North Road), 225½ m.; *London & South-Western railway* 4 runs, three of which were operated between Waterloo and Bournemouth (Central), 108 m.; *London & North-Western railway* 74 runs, the longest being between Euston and Rhyl, 209½ m.; *Midland railway* 25 runs, the longest from St. Pancras to Shipley (a stop to change engines only, not advertised) 206 m.; *North-Eastern railway* 14 runs, all between Newcastle and Edinburgh, working through over N.B.R. north of Berwick, 124½ m. Average speeds for the best of these runs were respectively: C.R. 49.7; G.E.R. 49.7; G.N.R. 57; G.C.R. 55.85; G.W.R. 54.8; L. & S.W.R. 54; L. & N.W.R. 52.7; M.R. 50.86; and N.E.R. 54.1 m.p.h. On several of these lines, however, trains making somewhat shorter runs provided even higher averages. The following non-stop runs exceeding 55 m.p.h. may be noted:—

		Miles	Minutes	Average
N.E.R.	Darlington to York	44½	43	61.7
G.C.R.	Leicester to Arkwright St., Nottingham	22½	22	61.3
L. & S.W.R.	Dorchester to Wareham	15	15	60
G.W.R.	Paddington to Bristol	118½	120	59.2
L. & N.W.R.	Wilkesden to Coventry	88½	92	57.7
G.N.R.	Grantham to King's Cross	105½	110	57.5
C.R.	Forfar to Perth	32½	34	57.2
M.R.	St. Pancras to Kettering	72	70	56.8
G.E.R.	Halesworth to Woodbridge	21½	23	56.6
C.L.C.	Manchester to West Derby	31½	34	55.1

It may be remarked that the short L. & S.W.R. run mentioned was due to an error in time-table compilation, but was worked for some time. The S.E. & C.R., L. & Y.R., and G. & S.W.R. had runs exceeding 54 m.p.h., while the Great Southern & Western and the Great Northern railways in Ireland, the L.B. & S.C.R., the London, Tilbury & Southend section of the Midland railway, and the Hull & Barnsley railway also had runs averaging 50 m.p.h. or over.

Many of the runs mentioned had been operated for several years before the outbreak of war in 1914, but in two cases at least, the highest level was reached between 1910 and 1914. Thus, on the Great Western railway, the opening of the Ashenden-Aynho line, shortening the distance between London and Birmingham to 110½ m., provided four down non-stop trains in the even two hours. These conveyed from one to three slip coaches, detached at Banbury, Leamington or Knowle, but the over-all time of two hours was also given to several up trains, though these had to include stops at Leamington or Banbury or both. On the London & North-Western railway a number of London-Birmingham trains were similarly accelerated to 120 minutes for the distance of 113 miles. On the London & South-Western railway two hours became the standard for Waterloo-Bournemouth non-stop trains as from July 3 1911.

Train Service Developments.—The following developments in train service facilities may be noted. On Feb. 1 1910 the L. & N.W.R. introduced "city-to-city" expresses between Wolverhampton and Birmingham and Broad Street. A novelty on these trains was the provision of a typewriting compartment, in charge of a qualified stenographer. In the following May similar arrangements were

introduced on certain Birmingham-Euston expresses. In July 1910 restaurant cars were introduced on through trains between Manchester, Birkenhead and Bournemouth, L. & N.W., G.W., and L. & S.W. railways. In July 1910 certain Midland Anglo-Scottish expresses were diverted to run over the L. & N.W.R. between Penrith and Carlisle. At the same time several Caledonian expresses to and from Aberdeen began to use Glasgow Central Station instead of Buchanan Street. In Oct. 1910 the G.W.R. introduced through trains via the Ashenden-Aynho line between Wolverhampton and Victoria, S.E. & C.R. In July 1910 the L. & S.W.R. improved their Southampton-Havre route to the European Continent. In May 1911 the S.E. & C.R. Continental service from Queenborough to Flushing was transferred to Folkestone. On June 1 1911 tea cars were introduced on the afternoon expresses between London and Manchester and Liverpool, L. & N.W.R. From July 3 1911 through carriages forming parts of S.E. & C.R. Kent Coast and other expresses were run to and from King's Cross, G.N.R. On the same date the N.E.R. introduced hourly expresses between Newcastle, Sunderland, West Hartlepool, Stockton and Middlesbrough. In March 1910 Metropolitan District trains commenced to work through over the Metropolitan railway to Uxbridge, and in June of the same year through trains between Ealing and Southend were added. In July 1913 the G.W.R. introduced the "Devon and Cornwall Special" express (third class only) between London and the West of England.

Pullman Cars.—Hitherto used only on the L.B. & S.C.R., on March 21 1910 Pullman cars were added to certain S.E. & C.R. Continental expresses via Dover, and in the following December to those via Folkestone. In June 1910 they were adopted by the Metropolitan railway on the extension line to Aylesbury. In June 1914 Pullman cars were introduced on a considerable scale by the Caledonian railway, some of them replacing first- and third-class restaurant cars, while others were available only for first-class passengers on payment of a supplement as usual. In Sept. 1915 the L.B. & S.C.R. added third-class Pullman cars to certain trains. From June 16 1919 Pullman cars were added to Folkestone and Kent Coast expresses, S.E. & C.R. In July 1921 the S.E. & C.R. added a special Pullman express, the "Thanet Limited," between Victoria and Ramsgate Harbour on Sundays. From Nov. 11 1920 Pullman cars began to run on the G.E.R. Both first- and second-class cars now run on its Continental expresses, and first- and third-class cars on other routes.

Withdrawal of Second-Class Accommodation.—Several railways had already withdrawn second-class accommodation, partially or wholly, before 1910, but in Oct. of that year the G.W.R. discontinued provision for second-class passengers. From June 1 1911 the L.B. & S.C.R. adopted the same course; the L. & N.W.R., Cambrian, North Staffordshire, and Maryport & Carlisle from Jan. 1912, and from July 22 1918 the L. & S.W.R.

Season Tickets.—In regard to season tickets several interesting items may be referred to. In May 1910 the G.W.R. commenced to issue season tickets at stations on application. In Dec. of the same year the G.N.R. discontinued calling for deposits on season tickets, this practice being now general on most lines. From Jan. 1 1912 the Metropolitan railway issued "limited season tickets" to the wives of season-ticket holders, a corollary to the shopping tickets which had been issued from Jan. 1910, available only between 10 A.M. and 4 P.M., the first-class fares being little more than for third class.

Working Arrangements.—Several important working arrangements and agreements between leading railways were already in operation as between the L. & N.W., L. & Y. and Midland railways, and in May 1910 a similar working arrangement was entered into between the G.W. and L. & S.W. railways. In Aug. 1912 the London, Tilbury & Southend railway was taken over by the Midland company, being thereafter known as the L.T. & S. section. In Oct. of the same year the Great Northern & City railway was incorporated into the Metropolitan system, and in Nov. 1912 the City & South London and Central London railways were brought into the group controlled by the Underground Electric Railways Co. of London, Ltd. In Jan. 1915 a reorganization of the "Underground" companies, co-ordinating the several managements, was adopted. In April of the same year the Great Eastern railway adopted a reorganization of the chief departments, while the operating and commercial departments were separated as from July 1 1915.

Strikes, etc.—In Aug. 1911 there was a short strike of railwaymen which led to the appointment of a special Royal Commission. The principal result of this was the establishment of Conciliation Boards, including representatives of the respective managements, of the various grades of staff and of the Board of Trade, for the purpose of dealing with questions of pay, duties and other problems affecting railway staff. In Sept. 1911 there was a strike of Irish railwaymen. In March 1912 a coal strike entailed many difficulties upon the railways, the Great Eastern being the only large company which was able to maintain approximately full train services throughout. In Dec. of the same year there was a strike on the North-Eastern railway owing to the suspension of a driver named Knox, for alleged drunkenness, but this did not spread to any serious extent. Knox was actually fined for being drunk by the Newcastle magistrates on Oct. 26. He was off duty at the time. But eventually an inquiry by Mr. Chester Jones, the London police-magistrate, resulted in his reporting (Dec. 14) that Knox (though "not quite sober") had not

been "drunk in the police-court sense," and he was then reinstated. In March 1913 the National Union of Railwaymen was formed from the Amalgamated Society of Railway Servants, the General Railway Workers' Union, and the United Signallers' and Pointsmen's Society. In Oct. 1913 a Royal Commission on Railways began its sittings, which were not completed at the outbreak of the war.

Railways Accounts and Returns Act 1911.—Commencing Jan. 1 1913, the Railway (Accounts and Returns) Act 1911 came into force, from which date the methods of preparing the annual returns of all railway companies were unified and systematized, and the previous half-yearly periods, with their Scottish variations, gave place to accounts and returns for the calendar year, providing for annual meetings in Feb. in every case. The year 1913 is the only one for which complete accounts and returns were prepared in accordance with the Act, the conditions of railway control and guarantee during and subsequent to the war having prevented later returns being presented in complete form. Indeed, during the actual war period the accounts and returns were reduced to bare essentials, and some tables are still necessarily in abeyance.

"Safety First."—In 1914 the Great Western railway adopted systematic "Safety First" propaganda, immediately followed by the London "Underground" railways, and since that date the matter has been closely followed up by other companies, several having issued publications to their staff setting forth "Safety First" principles. On Dec. 1 1916 the London "Safety First" Council was constituted, including representatives of several railways.

Locomotive Development.—Superheating was already recognized as a desirable feature of locomotive practice in 1910, and has since become firmly established as an essential part of almost every locomotive design, including tank and shunting as well as main-line passenger and goods classes. The Schmidt and Robinson types are both widely employed, the former in the hands of the firm known as Marine & Locomotive Superheaters, Ltd., and the latter in those of the Superheater Corp., Ltd. Both have been developed, and dampers or draft retarders are now seldom employed, improved designs of release, snifting and other valves or adjuncts, or the use of a steam circulating system, being found to meet the needs of the situation. The designs mainly used in each case are the types A and B of the respective firms. Several other designs are, however, now in considerable use; Mr. G. J. Churchward's "Swindon" apparatus on the Great Western railway; Mr. G. Hughes's "top and bottom header" and "twin plug header" designs on the Lancashire & Yorkshire railway; Mr. R. W. Urie's "Eastleigh" superheater on the London & South-Western railway; Mr. H. N. Greasley's "twin-tube" superheater on the Great Northern railway; Mr. R. E. L. Maunsell's special form of header (M.L.S. superheater, Type C) on the South-Eastern & Chatham railway; and Mr. E. A. Watson's design on the Great Southern & Western railway of Ireland. Mr. J. G. Robinson, of course, uses the "Robinson" pattern on the Great Central railway and his designs are largely used also on other railways. High-degree superheating is now invariably employed.

Feedwater heating is used to a limited extent on certain lines, and the Weir apparatus has been experimentally installed on several others, but the practice is still far from general. The use of oil for fuel continues to be the subject of experiment, but is still exceptional, though during the 1921 coal strike engines were adapted on many lines. Mention may be made of trials of the "Scarab" system on the L. & N.W.R. and other lines, while on the Great Central railway Mr. J. G. Robinson is stated to have obtained notable results from pulverized fuel and a "colloidal" mixture of pulverized coal and oil, also with the "Unolco" oil-burning equipment.

Recent locomotive practice tends towards the systematic adoption of the 4-6-0 type for express and ordinary passenger and fast-goods locomotives, while the 2-6-0 type has appeared on several lines for mixed-traffic duties. The former is often associated with the use of four high-pressure cylinders, and on several railways three-cylinder locomotives of various types have been placed in service, but the ordinary two-cylinder system is still the most general. Walschaert valve gear is becoming more and more widely used. On many railways large tank engines have been introduced, notably of the 4-6-2, 2-6-4, 4-4-4, 0-6-4, and 4-6-4 wheel arrangements, with 0-8-2 and 2-8-0 locomotives for heavy local goods and shunting work.

Rolling Stock.—In the carriage department there have been no special developments since 1910, though improvements in designs already in use have, of course, been made. To some extent, steel panels are being employed, and for electric rolling stock steel construction is now largely used. On the L. & Y.R. all-steel coaches are used on the Manchester-Bury electric route. To provide for rapid detraining and entraining of passengers at busy "Underground" stations, new designs of rolling stock have been adopted, including three sets of double doors on each side, one midway and the others towards, but some distance from, the ends. Steadying pillars and hand-holds are superseding the straps hitherto provided for the convenience of standing passengers. On the goods and mineral side no special developments in rolling stock need to be referred to, except that the use of high-capacity wagons up to 50 tons' capacity is extending, though as yet to a limited extent only.

Miscellaneous.—During 1910 express locomotives of the G.W. and L. & N.W. railways were exchanged for comparative trial; also

between the Highland and North British, the L. & N.W. and North British, and the Great Southern & Western and Great Northern in Ireland. On April 4 1914 the well-known horse "Dandy," which had so long worked the Port Carlisle branch of the North British railway, at last gave place to a steam train. On Dec. 19 1915 occurred the disastrous landslide at "The Warren," Folkestone, necessitating the closing of the S.E. & C.R. main line between Folkestone and Dover throughout the war period. It was not reopened until Aug. 11 1919.

BRITISH RAILWAYS UNDER WAR CONDITIONS

Railway Executive Committee.—As far back as 1865 an Engineer and Railway Staff Corps had been formed to provide an organization of railway managers, engineers and contractors who, in the event of war, would, under the direction of the military authorities, superintend the operation of railways and carry out such additional works as might be necessary. In 1896 the Army Railway Council was constituted, this body being known from 1903 as the War Railway Council. From these bodies was formed in Nov. 1912 the Railway Executive Committee, comprising the general managers of certain leading railways. The work of the Committee was mainly advisory, but included certain preparatory measures which bore good fruit when, on Aug. 4 1914, on the declaration of war, nearly all railways in England, Scotland and Wales were taken over by the Government under the Regulation of the Forces Act 1871, and directed on behalf of the State by the Railway Executive Committee. It may be explained that this Committee was never intended to supersede the actual management of railways, but to issue directions and to coördinate the working of all lines concerned as required by the various emergencies as they arose. Otherwise, and notwithstanding the many unanticipated developments in the scope and operation of the Committee throughout the war period, the ruling principle was always that the officers of the respective railways should continue to operate their lines without State interference.

Railway Control and Guarantee.—The Act of 1871 provided that, to avoid the complexities of payment for services rendered and other difficulties which necessarily would have arisen, the Government guaranteed to make up any ascertained deficiency in the aggregate net receipts of all the railways taken over as compared with the aggregate for the corresponding period of 1913. Throughout the war period, therefore, all ordinary financial arrangements on the operating side ceased, and the work of the Railway Clearing House in regard to the division of receipts according to ownership of lines and various arrangements between companies was discontinued. The original agreement provided for adjustment according to the conditions during the first half of the year 1914 as compared with the corresponding period in 1913, but, when the question of war bonuses to railway workers to meet the higher cost of living arose early in 1915, it was agreed that this proviso should cease to operate in consideration of the first 25% of the war bonus conceded in Feb. 1915 being borne entirely by the companies, though all subsequent increases were undertaken by the State. In Aug. 1915 the Government accepted the principle of making allowances to the railway companies supplementary to the periodical compensation payments in respect of deferred maintenance and renewal. At a later stage agreements were made as to the payment of interest upon various capital works unproductive at the time of the outbreak of war, or completed and brought into use during the earlier war period, and in regard to many other complicating factors which arose. Some of these agreements occasioned severe strictures by Lord Colwyn's Committee on

Railway Agreements, whose report was issued early in 1921, but during the period of hostilities, and notwithstanding the very wide and to some extent undefined scope of control which was eventually forced upon the Railway Executive Committee, the arrangements made by the Committee on behalf of the State with the railway companies are generally regarded to have been reasonable and equitable.

The Government Profit on Railways.—It may be pointed out that, according to a Government return issued under date of April 30 1919, if all Government traffic had been charged for at authorized pre-war rates the amounts would have been as follows for the periods stated:—

Aug. 5 to Dec. 31 1914	£ 3,300,000
Year 1915	10,279,104
Year 1916	20,649,126
Year 1917	35,698,554
Year 1918	41,917,024
Total	£112,043,808

For the corresponding periods the amounts which the Government had to provide by way of compensation were:—

Aug. 5 1914 to Dec. 31 1915	£15,946,839
Year 1916	14,039,674
Year 1917	24,075,768
Year 1918	41,251,326
Total	£95,313,607

Beside the actual working of the railways, the use of railway steamers, docks, canals, etc., represented a value estimated at from £10,000,000 to £15,000,000, while munition and similar work done (to the value of about £17,000,000) in railway workshops at cost price and therefore without profit to the companies, also the provision of locomotives, rolling stock, permanent way, etc., for use overseas, indicate the complexities of the arrangements ultimately entailed and the tremendous scope the utilization of the home railways for war purposes eventually attained. The Irish railways were not concerned at first in the Government control and guarantee. They were, however, taken over under similar conditions from Jan. 1 1917. The appended table shows the manner in which the control of railways in association with the Government guarantee operated.

In other words, the aggregate of all the freight, munition, troop and passenger traffic carried on Government account, if charged for, would greatly have exceeded the sum payable by the Government to bring up the annual net receipts to the pre-war level. It has to be remembered, however, that arrears of maintenance and cost of replacement of stock, etc., apart from what was essential at the time, could not figure very prominently in the accounts until after the termination of hostilities. After the Armistice, however, heavy costs were entailed under these and other headings, while the reduction of Government traffic to the relatively very small figures of the post-war period converted the profit of the war years into a serious deficit. The fact remains, however, that while the war emergency continued the bargain made was a very good one for the State, and it was only in 1918 that the, by then, generous wage and war-bonus concessions to the railway staff tended to convert the profit to the State into a deficiency—even then a relatively small one.

War Bonuses and Concessions to Staff.—As showing the tremendous effect of these concessions it may be mentioned that for the financial year ended March 31 1920, as compared with 1913, the increased cost of working the railways was estimated at £57,000,000 on account of war wage and other concessions, and

OPERATION OF GOVERNMENT GUARANTEE

	1915	1916	1917	1918
Revenue earned by railways over expenditure ¹	45,171,403	49,420,063	53,885,849	44,068,105
Amount of compensation paid by Government to railway companies on basis of published accounts for 1913	46,130,000	46,319,000	46,515,000	46,576,000
Profit or Loss to Government	-958,597	+3,101,063	+7,370,849	-2,507,895

¹ Includes estimated value of services rendered by railways to the Government free of charge, as shown in White Paper, Cmd. 402, apart from value of services rendered to the Government in respect of steamboats, canals, docks, hotels, etc., estimated at from £10,000,000 to £15,000,000 for the war period.

from £20,000,000 to £25,000,000 due to the eight-hour day and further concessions then recently granted or under discussion. In the opinion of experts it is thought, however, that even these difficulties would not have arisen, at least in so acute a form, had it not been for the maintenance of pre-war rates and charges for goods traffic throughout the war period, while it was not until Jan. 1 1917 (June 1 1918 in Ireland) that ordinary passenger fares were increased by 50 per cent., and then mainly with the object of restricting travel rather than of raising revenue. Had adjustments been made stage by stage, as was done in the case of prices in general trade and industry, the financial situation in regard to railways would have been very greatly improved, and there would have been relatively little objection to the increase which became imperative in the post-war period.

Mobilisation Traffic.—Very complete plans for mobilization had been prepared by the Railway Executive Committee long before there was any probability of war, and continually revised and brought up to date, so that everything was ready for the wonderful transportation achievements which followed the declaration of war. Thus between Aug. 10 and 31 no fewer than 670 trains, coming from all parts of the country and conveying horses, guns, baggage and stores, as well as approximately 120,000 men of all ranks, were dealt with at Southampton Docks with little interference with ordinary civilian traffic. Throughout the war period achievements of this character were regularly accomplished at all the chief embarkation centres and there is no instance on record of the breakdown of railway arrangements at any time, even when the tremendous volume of munition and other traffic conducted in national interests, but not directly for war purposes, was also placed upon the railways.

Public Railway Transport.—During the war period it was necessary to impose many restrictions upon both passenger and goods traffic. Excursion and many cheap-fare facilities were early discontinued, as also tourist and certain other classes of tickets carrying special facilities. Continental traffic was, of course, subject to special regulations and from the outbreak of war Dover became a closed area, such continental steamer services as were maintained being diverted to other ports. In fact, at all the great railway ports there were severe restrictions upon civilian traffic. During 1916 further regulations came into force for passenger travel, following a process of deceleration of express trains, partly due to the insertion of stops to enable them to serve the purpose of trains which were withdrawn in order to free the lines for Government traffic, and partly in view of the exceptional loading which became general, and to ease the strain on permanent way, bridges, etc., which could not be maintained to usual standards. From Jan. 1 1917 still further restrictions were imposed upon railway travel and conveyance of luggage; restaurant cars were withdrawn entirely on many lines and reduced on others, and passenger traffic was allocated to specific routes where alternatives had hitherto been available for the same journeys. An increase of 50 per cent. was made upon ordinary passenger fares and from 10 to 20 per cent. on season tickets, the issue of which was regulated, while it was required that they should be shown by each passenger on every journey made. Certain branch lines were closed, most of the rail-motor intermediate services withdrawn, and a large number of stations closed.

Release of Railwaymen.—An important object of these reductions in train services and facilities was to enable railwaymen to be released to serve with the forces, and altogether no fewer than 184,475 men were thus contributed. This figure represented 49 per cent. of the staff of military age in railway employ on Aug. 4 1914. Large numbers of men, apart from Reservists and Territorials, had, of course, joined voluntarily quite early in the war, but the general enlistment of railwaymen was not favoured until 1916, by which time a definite scheme of release had been adopted on a system which reduced inconvenience to the railway companies to a minimum and yet enabled reasonable proportions of men to be supplied.

Railway Officers in Government Service.—Throughout the war railway officers of many grades were freely utilized by the Government, some for special duties involving commissioned rank in the army or navy, and others for rendering expert assistance in civilian capacities to various Government departments. In fact, a considerable number of railway officers in high positions were given

important Government appointments in connexion with various existing and new State departments. In other instances, railway officers were temporarily loaned to the Government.

Employment of Women.—Comparatively early in the war women were introduced into many ranks of the railway service, and in due course they were seen on a wide variety of work—at passenger and goods stations and depots, in engine sheds, on electric trains as "gatemens" and in a few instances as guards, on cartage and delivery vans, and in the railway workshops, in addition to more obvious employment as clerks, waitresses and in booking-offices. To some extent these measures were rendered practicable by the discontinuance of the more complicated travel facilities, the reduction of record-keeping to a minimum, the abolition of detailed statements between railway companies and Railway Clearing House work; but to a great extent women were employed in direct replacement of men who had been released with but little adjustment of their duties. A total of 55,000 women were thus employed in railway working, and about 6,000 on munition work in railway shops.

Goods and Mineral Traffic Allocation.—Goods and mineral traffic, especially when the manufacture of munitions on a very large scale was going on all over the country under Government direction, became of vital importance, and all other traffic was made subservient thereto. For the control of non-Government traffic a system of allocation was widely adopted, requiring consignors to despatch their goods by specified routes and from particular depots and sometimes on particular days, according to destination, while at times it was necessary to refuse to accept traffic for a time. Arrangements had already been made between the leading railway companies in regard to "common user" of wagons of ordinary type, while private owners' wagons were brought into the "pool."

Coal Control.—A system of coal control was adopted in 1917, partly due to the necessary discontinuance of a large proportion of the normal coastal water-borne conveyance of coal, by which each part of the country drew its coal supplies from specified colliery areas, and this traffic alone represented an enormous burden.

Military and Naval Traffic.—For the needs of the Army and Navy facilities on a very large scale had to be provided. Apart from the movements of troops for service overseas, continual streams of traffic passed to and from the training camps. Leave travel, however restricted, was inevitably a very big factor, and, as the war progressed, ambulance trains passed very frequently between the Channel ports and hospitals in various parts of the country. Among special facilities which had thus to be afforded may be mentioned the naval leave trains which ran regularly between the north of Scotland and London in connexion with the fleet in northern waters, while a continuous stream of coal trains had to be run between South Wales and other suitable coal areas and the far north of Scotland for the use of naval vessels. One of the chief difficulties, indeed, was the need for using the Highland railway for naval traffic on so large a scale, and parts of this were doubled during the war in order to relieve the congestion which necessarily followed the lengthy single-track mileage of this, as it proved, vitally important line.

Munition Traffic.—Widespread munition manufacture necessarily occasioned a great deal of civilian traffic directly and indirectly in national interests, while in a number of places ordinarily quiet stations or branches became very busy owing to the erection of army camps or of munition works. A few stations had to be specially erected and several new branch lines made.

Railway Docks and Harbours.—As owners of several of the best-equipped docks and harbours, including new ones such as Immingham, G.C.R., and the King George Dock at Hull, I.L. & B. and N.E. Railways, and the new lock entrance at Newport, Alexandra (Newport & South Wales) Docks & Railway, brought into use shortly before the outbreak of war, in addition to the older ones, such as Southampton, the railways provided the nation with some of the most complete embarkation depots. Most of these became closed areas, and all of them were used to their fullest capacity, either for direct war traffic or when the submarine menace diverted shipping traffic from its accustomed ports.

Railway Steamers.—Railway steamers also were widely used, and of a total of 218 vessels 126 were taken over and 36 lost from various causes. They were used as transports, for the maintenance of national supplies, as minesweepers, and as hospital ships. Frequently even those which remained on regular services had to assist in meeting emergencies, such as the evacuation of Belgian refugees.

Railways and Air Raids.—An important difficulty with which the railways had to deal was that due to the numerous air raids over Great Britain. Relatively little serious damage was done, but the fact that traffic had often to be or worked under difficulties, the reduced lighting generally maintained throughout the more vulnerable parts of the country, and the congestion which followed each cessation of traffic constituted serious hindrances to railway working.

Armoured Trains.—Throughout the war period, too, the possibility of invasion had to be faced, and many special arrangements made with a view to the possible need for transferring the civilian population from the coast towns to the interior. Several armoured trains were constructed in the railway workshops, though they were never called upon for use under service conditions.

Miscellaneous.—At many of the principal railway stations free buffets were installed for the benefit of soldiers and sailors, and in

some cases these provided special facilities, as at Victoria, S.E. & C.R., where arrangements were made for the exchange of French for English money, the amount dealt with reaching a total of approximately £10,000,000. At one period the railways were severely congested by the traffic due to the evacuation of Belgium, and one result of this was the continual stream of Belgian soldiers coming to England on leave to visit their families, a total of 237,000 thus travelling. At many stations local bodies, such as the V.A.D., etc., made very complete arrangements for providing refreshments to soldiers travelling through and for attendance upon the ambulance trains. Frequently valuable assistance was given by the various ambulance associations belonging to the railway service.

BRITISH RAILWAY WORK IN THE WAR

During the war period British railways rendered essential services on a very large scale, both in regard to traffic requirements at home and those associated with active service in the various war areas. To some extent the former has already been covered by general reference, but further details must be given.

Military and Naval Special Trains.—Between the declaration of war and the date of the Armistice all the larger railways were called upon to run special trains conveying officers and men, frequently with guns, ammunition, horses and equipment, when passing to a port for embarkation to France or other theatres of war. There were also transfers of units between camps, leave travel and special events, such as the arrival of Canadian, S. African and other contingents from abroad and their journeys from ports of arrival to training centres, together with that portion of the American army which passed through the United Kingdom. In the aggregate the numbers of special trains operated by the leading railways were very great, and the following table shows, as far as information is available, the number of special trains mainly, if not exclusively, on the passenger side, run by the railways mentioned, with the numbers of officers and men who travelled:—

	Trains	Officers and Men conveyed
L. & S.W.R.	58,850	20,223,954
L. & N.W.R.	56,470	22,268,000
G.W.R.	33,615	—
N.E.R.	24,172	11,810,290
L.B. & S.C.R.	27,366	—
G.E.R.	13,000	6,231,293
G.C.R.	5,663	2,636,726

Three other railways may be mentioned, though their totals include also ambulance trains, goods and other specials:—

	Trains	Officers and Men conveyed
S.E. & C.R.	163,000	12,141,933
M.R.	11,502	2,282,000
N.B.R.	45,000	—

The numbers of special trains required on the freight side are more indefinite, as they included many trains run to meet the needs of the Government munition undertakings and of coal traffic passing from the colliery areas to the Fleet bases, and, to some extent, in connexion with the coal control scheme. However, it may be mentioned that on the London, Brighton & South Coast railway no fewer than 53,376 special trains were run mainly for traffic to and from the ports on the system. On the Great Western railway the total was 63,349 and on the Great Eastern railway 11,000. To meet the needs of the Fleet several railways ran 20 or even more trains per day conveying Admiralty coal. The arrival of the American army in Great Britain entailed the running of 1,684 special trains on the London & North-Western railway and 1,130 on the Great Western railway. When the Canadian contingents first arrived in England the London & South-Western railway was required to run 92 specials from Plymouth alone.

Ambulance Trains.—For home service a total of 20 trains was equipped for army use: G.C.R. 3; G.E.R. 2; G.W.R. 4; L. & Y.R. 2; L. & N.W.R. 5; L. & S.W.R. 2; M.R. 2. There were also two in Ireland, one each equipped by the G.N. and G.S. & W. railways. Five naval ambulance trains were also in use, these differing somewhat in regard to internal arrangements and equipment. Many individual vehicles were also fitted for the purpose of conveying small numbers of men in ordinary trains, and there were nine other trains

sufficiently equipped to be brought into use as emergency ambulance trains. For service overseas 30 ambulance trains were equipped by the home railways, each consisting of 16 bogie coaches. These were supplied as follows: G.C.R. 1; G.E.R. 4; G.W.R. 6; L. & Y.R. 3; L. & N.W.R. 7; L. & S.W.R. 1; L.B. & S.C.R. 1; M.R. 2; N.E.R. 1; L. & N.W.R. and G.E.R. 1 jointly; L. & N.W.R. and L.B. & S.C.R. 1 jointly. Two trains presented by the United Kingdom Flour Millers' Association were constructed by the G.E. and G.W. railways jointly, and the Lord Michelham (or "Queen Mary") presentation train was equipped by the L.B. & S.C. and L. & N.W. railways. A further train, known as the Princess Christian Hospital Train, was built by the Birmingham Carriage & Wagon Company. A majority of these trains was employed in France, but two went to Egypt and one to Salonika. When the American army came arrangements were made for 19 other trains, of the same general type as those previously supplied for overseas service, to be equipped by British railways for the use of the U.S.A. forces in France, as follows: G.C.R. 1; G.E.R. 1; G.W.R. 4; L. & Y.R. 3; L. & N.W.R. 4; L. & S.W.R. 1; M.R. 5. Twenty-nine others were on order at the date of the Armistice, when, of course, work was at once suspended. Including spare and extra vehicles, a total of 822 vehicles was thus adapted for the Government trains, and 304 for the U.S. trains.

The following numbers of journeys made by ambulance trains on various railways will indicate the enormous volume of this traffic, these figures applying, of course, only to the ambulance trains running on the home railways: L. & N.W.R. 13,318; L. & S.W.R. 10,173; S.E. & C.R. 7,515; G.W.R. 5,000; M.R. 3,982; N.B.R. 1,800; G.E.R. 1,172. This traffic was dealt with at various ports, but it is worthy of note that no fewer than 3,166 were despatched from the new Marine station at Dover, uncompleted at the time of the outbreak of war, but finished off at an early date sufficiently to serve for the transfer of wounded men.

Troop Movement and other Military Traffic.—The numbers of special trains given above will indicate the enormous dimensions which the traffic entailed by troop movement involved. At suitable places large numbers of both passenger and goods vehicles had to be kept in reserve to provide for movements of troops at short notice, and many of the cross-country or connecting lines proved of special value in enabling through journeys to be made from one system to another and by providing alternative routes to avoid congestion. The North London, Hainstead Junction, and North and South-West Junction railways carried nearly 14,000 special trains, and on several dates public traffic was entirely discontinued. The "widened" lines of the Metropolitan railway, through Farringdon Street and the connexion to the South-Eastern & Chatham railway at Ludgate Hill, were used by no fewer than 626,000 special passenger or goods trains, though this route was restricted by the limited loading gauge and could not, therefore, be used for ambulance trains and certain other traffic. The West London railway dealt with about 150 troop or special trains per month, and the East London a gross total of about 1,000. Bearing in mind that the magnitude of the forces involved a tremendous amount of leave travel, it may be mentioned that, during 1917 only, over 28,000,000 of H.M. forces travelled free by warrant on the home railways, while nearly 2,000,000 journeys were similarly made by civilians in Government service.

Traffic at Ports.—Dover was largely used as a centre for ambulance train traffic, but at Southampton a very large volume of stores, munitions and other material was dealt with, besides a considerable amount of shipping traffic necessarily continued. The Southampton train ferry to Dieppe was brought into use in Nov. 1917, that at Richborough, near Sandwich, being completed in Feb. 1918. Both enabled goods wagons to be sent across without transshipment, and they were especially useful for the conveyance of tanks, heavy guns, locomotives, etc. Avonmouth, Devonport and Liverpool were used as ports for supplying the Mediterranean and Mesopotamian forces. Immingham and other East Coast ports were largely used for supplying the fleets in more southern waters, while Leith, Aberdeen, Invergordon, Thurso and other Scottish centres were kept very busy in meeting the demands of the Grand Fleet. Newhaven and Littlehampton together dealt with nearly 7,000,000 tons of traffic on war account. In addition to the steamer traffic across the Channel the South Coast ports, including Richborough, sent over 1,000,000 tons by means of sea-going barges.

Munition and Admiralty Coal Traffic.—Besides the traffic directly required for the army and navy, the railways had to meet many other traffic requirements, as indicated by the following: The South-Eastern & Chatham railway alone conveyed nearly 200,000 tons of army mails, parcel-post packages and lighter stores not dealt with in bulk, via Dover and Folkestone. On the London & North-Western railway nearly 16,000 trains were run for the conveyance of Admiralty coal. In many parts of the country extensive forestry work was undertaken, and the conveyance of the cut timber amounted to hundreds of thousands of tons on many railways. On the North-Eastern railway the tonnage of goods conveyed on Government account amounted to 5,500,000, and of Admiralty coal nearly 12,000,000 tons, while to serve the numerous munition centres in the north-eastern area involved the conveyance of some 84,000,000 workpeople. On the Great Western railway at one time no fewer than 350 additional trains had to be run daily, solely for the conveyance of workers to the various war factories.

Locomotives and Rolling Stock sent Overseas.—A number of locomotives under construction for various colonial and foreign railways were commandeered by the Government and diverted for use in France and elsewhere, while large orders were given for the building of engines by British firms for use in France. A total of 247, of a contemplated order for 500 of the 2-8-0 type alone, was constructed. But to meet immediate needs it was necessary for British railways to supply considerable numbers of engines from their own stocks, mainly for France, though some went to Egypt, Mesopotamia, and Salonika. The total locomotives thus supplied numbered 675, of which the L. & N.W.R. provided 111; G.W.R. 95; M.R. 78; N.E.R. 50; G.C.R. 33; and G.N.R. 23; the remainder being sent by other companies. In addition, 30,000 goods wagons were sent overseas, together with 100 special wagons and 40 30-ton coal wagons. The Great Central railway constructed six engines to the design adopted for the War Department 2-6-0 locomotives which were, in fact, substantially to G.C.R. designs; 2,500 20-ton covered wagons were built in railway workshops.

Besides the standard-gauge rolling stock, large numbers of steam, petrol, and petrol-electric locomotives of small types, and wagons of various designs, for use on the light railways in France, were built by various firms, though not much of this work was done by the railway companies beyond the equipment of Ford cars as rail tractors at Crewe Works. A considerable amount of permanent way was, however, sent overseas by the home railway companies, partly by taking up certain light-traffic branch lines or by converting double lines to single track, and also to a considerable extent from stock. A great quantity of bridge parts, machinery, cranes and other material was also supplied from stock, while the equipment of the army railway workshops in France was largely provided by the various railway companies.

War Work in Railway Shops.—As already mentioned, this was undertaken to the value of about £17,000,000, and covered a wide range of products—from ambulance stretchers, road vans and gun-carriages to the repair of cartridge cases and the production of shell cases, frequently of large sizes. Several travelling workshop trains were also equipped in the British railway shops. In a number of instances, too, railway companies undertook the repair of Belgian and other locomotives sent over from France.

The Railway Troops.—As already mentioned, a total of 184,475 men was released from railway service to join H.M. forces. They were largely utilized in the formation of, or transferred to, the various sections known generically as the Railway Troops attached to the Royal Engineers. A number of the companies were recruited mainly from the men of a particular railway, especially in the case of the L. & N.W.R. (115th) and the G.W.R. (116th, 262nd and 275th), while the 118th was recruited chiefly from the G.E. and N.E. railways. There were two principal sections, the Railway Construction Troops and the Railway Operating Division, the former numbering 35 companies and the latter 42½ companies, including those dealing with the light railways. Besides these there were Labour, Roads, Canadian Overseas Construction, Canadian Operating, S. African and Australian companies, bringing the total to 118½ companies. The various camp railways were also supplied from these bodies.

THE POST-ARMISTICE PERIOD

On the cessation of active hostilities the pressure of war traffic at once eased, though it was some weeks before Government traffic materially decreased in volume. Necessarily, for some time afterwards the completion of work in hand and the traffic occasioned thereby kept the railways fairly busy, though with less urgency and strain. Leave travel was even more freely given, and the demobilization of the forces for many months placed a big strain upon the railways on the passenger side. National traffic on the goods side, too, remained heavy, as systems of control of food-stuffs, coal and necessities could not at once be discontinued, and was further complicated by the public call for the return of unrestricted transit conditions, for improvements in facilities, and for a resumption of the relative freedom of pre-war conditions. There were also tremendous arrears of construction and maintenance of railway permanent way and rolling stock to be overtaken.

Demobilization of the Forces.—This traffic was a very big thing in itself, and numerous special trains had to be run between the ports and the demobilization centres. It was estimated that 40,000 men would be dealt with daily, and that was about the number realized. But the effect of public pressure caused great irregularity, and, as a result, the railways had to deal with much of this traffic—which also included the dispersal journeys of men from the demobilization centres—as best they could. One dispersal depot alone thus dealt with over 1,000,000 men. Horses had also to be conveyed in large numbers, many being brought back in through trucks *via* the Channel train-ferries.

Their sale, also the large traffic occasioned by the return of rolling stock and material from overseas, and the sale of army stocks of all kinds under the direction of the Disposals Board, added appreciably to the work of the railways.

Arrears of Maintenance and Construction.—The work thus involved was necessarily of great volume and expense. It entailed relaying of lines, repair and reconstruction of bridges, completion of deferred new works, repair of locomotives and rolling stock, and the construction of overdue replacements. In addition certain war extensions had to be dismantled, and workshops cleared of special machinery, and not a few new machines added in place of those which had become worn out. Public opinion ceased to look quite so favourably upon the large expenditure thus incurred. The companies had, of course, placed to reserve large sums in view of this work, but as they had been limited to net receipts on a pre-war basis, these were necessarily on pre-war standards, though usually with increases as far as practicable, whereas when the money had to be spent costs of materials and labour had increased approximately threefold. Agreements made between the Government and the companies provided for the difference being made up, but the amounts involved became so great that in Oct. 1920 a Committee was appointed to report upon these agreements. In large measure this was little more than a sop to public opinion, for the report of Lord Colwyn's Committee, as it is generally called, took little account of the merits of the case, and appeared mainly concerned with a solution which presented very much the appearance of repudiation of agreements when they became unpleasantly expensive. However, it was generally realized that these costs were the inevitable corollary to the great benefits, and actual profit as shown in a previous section, obtained by the nation from the railways during the war period; and a settlement was ultimately arrived at in May 1921, providing for the payment in two instalments of £60,000,000, after the termination of Government control in Aug. 1922. Until then the arrangements already adopted for monthly payments in respect of arrears of construction and maintenance were continued. This solution avoided much prospective litigation and represented a reasonable degree of give-and-take on both sides. The Colwyn Report suggested that a total of £156,000,000 would thus be involved, but this was given without data and was almost certainly overstated. Payments already made must be considered in conjunction with the £60,000,000 accepted in settlement. The corresponding amount agreed upon in respect of the Irish railways was £3,000,000.

Railway Guarantee and the Subsidy.—As Government traffic diminished in volume, and more and more national traffics were returned with de-control to private enterprise, the effect of the high cost of materials and supplies, and the generous wage and other concessions, quickly resulted in the railways requiring considerable subsidies. At the end of 1919 belated action was taken to increase railway charges to an economic level, the lack of which action had largely caused the very serious position which arose after the conclusion of active hostilities. Thus, whereas the amount of Government compensation in 1918 was £46,576,000, and the receipts, including the estimated value of Government traffic, £44,068,105 on account of railway working alone, for the year ended March 31 1920 the realized deficit amounted to £1,349,530, even after allowing for certain increases in charges which came into force during that period. And for the 1920-1 period the net Exchequer liability was estimated at £54,500,000.

Wage Concessions and Increased Costs.—These provide the chief explanation for the large subsidies entailed, expenses having risen nearly 200% and receipts an average of only 80% as compared with 1913, the year upon which the Government guarantee of net receipts was based. Thus the gross receipts, expenditure and net receipts for 1913, 1919 and 1920 were:—

	1913	1919	1920
Gross Receipts	£129,194,000	£226,363,000	£298,249,000
Expenditure	£83,385,000	£180,098,000	£251,575,000
Net Receipts (Railway)	£45,809,000	£46,265,000	£46,674,000

In the case of four representative railways, English, Scotch, Irish and Welsh, wages and salaries alone showed the following increases:—

	1913	1920
London and North-Western	£6,000,000	£20,000,000
North British	£1,660,000	£6,600,000
Great Northern (Ireland)	£357,000	£1,406,000
Taff Vale	£384,000	£1,187,000

War-time concessions consisted mainly of the flat-rate allowances of 33s. per week, reached by successive increases in view of the rising cost of living, but after the Armistice action was taken by the Railwaymen's Unions in respect of the eight-hour day (granted from Feb. 1 1910), standardizing of wages and grading. The eight-hour day caused many difficulties and is necessarily costly, especially as it had to be equalized for many men whose wages were not calculated on that basis. Throughout 1919 there were continual labour difficulties, and a serious strike lasted from Sept. 26 until Oct. 5, settled by an agreement that no reductions in wages should occur before Sept. 30 1920, and the whole matter thoroughly explored. In Oct. 1919 Central and National Wages Boards were set up. In Jan. 1920 an agreement was announced providing for an addition to the wages of each grade of 38s. per week and for cost of living allowances rising or falling in accordance with Board of Trade figures, with standardized rates of pay which should not fall below 100% over pre-war rates. This was at first objected to, but was accepted on Jan. 15 1920. Subsequent negotiations dealt with supervisory and other grades. Certain further advances were given in June 1920, and in view of the accompanying costs of materials and supplies it will be understood that these additions much more than balanced the alleged railway "subsidies."

Ministry of Transport.—An announcement, apparently unauthorized, by Mr. Winston Churchill in Dec. 1918, that nationalization of the railways was contemplated caused a great deal of misunderstanding. There were, however, many matters requiring attention, and these together resulted in the bill for establishing a Ministry of Ways and Communications presented to Parliament in Feb. 1919. As first introduced its contemplated scope and powers were considered to be too far-reaching, but in a modified form it was passed as the Ministry of Transport Act, receiving Royal Assent on Aug. 26 1919, the Ministry being established as from Sept. 23 1919. The Ministry took over several sections of existing departments, including the Railway Department of the Board of Trade and the Roads Board. The Railway Executive Committee continued as such until Jan. 1 1920, but most of its members were retained on the Railway Advisory Committee. Various other advisory and reporting committees have since been established.

Rates, Fares and Charges.—Apart from the 50% increase in ordinary passenger fares, and of 10 to 20% increases in season-ticket charges, railway rates remained as in pre-war years until the Ministry of Transport announced increases in demurrage rates as from Jan. 1 1920, and of 50% on goods rates as from Jan. 15 1920. These were followed on Aug. 6 by further increases bringing ordinary passenger fares up to 75% and season tickets 50% over pre-war rates, and from Sept. 1920 workmen's tickets were increased, and goods rates raised to substantially 100%. On Dec. 22 1920 the Rates Advisory Committee of the Ministry of Transport reported on the general question of rates and charges, and their recommendations materially influenced the Railway Bill placed before Parliament on May 11 1921.

Grouping and the Future of Railways.—One of the provisions of the Ministry of Transport Act was that a policy for the future of the home railways should be promulgated within two years. An outline of proposals was issued in July 1920, suggesting, *inter alia*, the amalgamation of railways into groups as follows: (1) *Southern*, combining the South-Eastern & Chatham, the Brighton, and the South-Western; (2) *Western*, the present Great Western system with the Welsh lines; (3) *North-Western*, combining the North-Western, the Midland and the Lancashire & Yorkshire, North Staffordshire and Furness; (4) *Eastern*, combining the Great Northern, the Great Central, and the

Great Eastern; (5) *North-Eastern*, the present North-Eastern system and the Hull & Barnsley; (6) *London Group* (local lines); and (7) a *Scottish Group* for the whole of Scotland. These proposals were severely criticized, and the Railway Companies' Association adopted the following alternative: *Group 1*, London & North-Western, Midland, Lancashire & Yorkshire, North Staffordshire, Furness, Caledonian, Glasgow & South-Western, and Highland railways; *Group 2*, Great Central, Great Northern, Great Eastern, Hull & Barnsley, North-Eastern, North British, and Great North of Scotland railways; *Group 3*, Great Western and Welsh lines; *Group 4*, London & South-Western, London, Brighton & South Coast, and South-Eastern & Chatham railways; *Group 5*, London railways (local lines). On May 11 1921 the promised bill was placed before Parliament, and embodied the following modified scheme: (1) *Southern Group*, London & South-Western, London, Brighton & South Coast, South-Eastern, and London Chatham & Dover railways; (2) *Western Group*, Great Western and Welsh railways; (3) *North-Western and Midland Group*, London & North-Western, Midland, Lancashire & Yorkshire, North Staffordshire and Furness railways; (4) *North-Eastern and Eastern Group*, North Eastern, Great Central, Great Eastern, Great Northern and Hull & Barnsley railways; (5) *West Scottish Group*, Caledonian, Glasgow & South-Western and Highland railways; (6) *East Scottish Group*, North British and Great North of Scotland Railways. During proceedings in Committee of the House of Commons the 5th group was combined with the 1st, and the 6th with the 2nd, substantially as proposed by the Railway Companies' Association, and the Act, which received Royal Assent on Aug. 10 1921, therefore provides for four groups only:—Southern; Western; North-Western, Midland and West Scottish; North-Eastern, Eastern and East Scottish. Amalgamation is to become effective on July 1 1923. The proposed London group was dropped in view of proposals for the setting-up of a London Traffic Board. Provisions were also made for the inclusion of representatives of the Railwaymen's Unions in association with railway officers on advisory councils, etc. (not as directors as at first claimed), and for the continuance of the Central, National and local Wages Board. It was considered that these provisions, some of which represented agreements already made in conjunction with the fare and rate increases in force according to the proposals of the Rates Advisory Committee, would enable the railway companies to operate under solvent and economic conditions on the termination of control on Aug. 15 1921. In regard to amalgamation it may be mentioned that early in 1921 preliminary arrangements of this character had already been made in regard to the North-Eastern and Hull & Barnsley railways, and the London & North-Western and Lancashire & Yorkshire railways, in addition to several smaller companies to be absorbed by their larger neighbours. The chief difficulty, in fact, was in regard to Scottish railways, which, it was claimed, would be so seriously affected that they could not hold their own in a group by themselves, the alternative of amalgamation with appropriate associated English companies being favoured. Hence the altered grouping adopted by the Act as finally passed. Control was actually terminated at midnight on Aug. 15 1921.

Restoration of Facilities.—During the war many usual facilities of travel were withdrawn, but during 1920-1 a number were restored, as follows: pre-war luggage allowance for passenger-train traffic, June 14 1920; passengers' luggage in advance, July 1 1920; day excursion tickets, Aug. 12 1920; period excursion tickets, Dec. 24 1920; week-end tickets, May 11 1921 (deferred, owing to the coal strike, until Aug. 20, and Aug. 19 in the case of commercial travellers). (G.E.R. continental services were resumed Feb. 25 1919; L.B. & S.C.R., June 1 1919; the Dover-Calais route, S.E. & C.R., Jan. 8 1920; and the Hull and Zeebrugge route, N.E. and L. & Y. railways, May 14 1920. Express-train running was rapidly restored to a good level during 1920, and though still below pre-war standards the main line services on all routes became very creditable in July 1921, both for speed and number. On some lines, indeed, pre-war schedules were definitely reinstated, and in certain instances facilities were even better than before the war. The suburban traffic problem was, however, still serious. On the "Underground" lines new rolling stock, when delivered, materially eased the inevitable congestion. An arrangement had been made during the war whereby the associated "Underground" railways, of which the

Metropolitan District only was controlled and subject to Government guarantee, should pool their receipts, including also the London General Omnibus Company. To meet the peculiar conditions of the situation a special Act of Parliament was passed, and from Sept. 26 1920 these lines were empowered to charge "revised fares," the Metropolitan District railway ceasing to come under the guarantee. Allocation of passenger travel to specific routes, already partly in desuetude, partially disappeared during the early months of 1921, and finally in July of that year.

Goods Traffic.—During 1920 most of the special regulations imposed under war conditions disappeared, though the common-user of wagons still continued, and by cooperative action it had become possible to realize a higher standard of wagon loading. Commencing with the four weeks ending Jan. 29 1920, the Ministry of Transport commenced to issue detailed statistics of goods traffic operation, and on the completion of twelve months these were altered to agree with the calendar months, in combination with corresponding passenger traffic statistics. (J. A. K.)

UNITED STATES

The decade 1910-20 was marked by many fundamentally important developments in organization, management, and public regulation of American railways. During the early part of the period a tendency, which had begun during the latter half of the preceding decade, toward a decreasing rate of return on the investment in railways caused serious financial distress and a marked decline from the normal rate of development of railway facilities, equipment and service. The years 1915 and 1916 brought large increases in freight tonnage through the transportation of war materials for the Allies. The active participation of the United States in the World War, beginning in April 1917, made even greater demands upon facilities already overtaxed. To meet these demands the railways tried the experiment of voluntary unification through a committee of railway presidents clothed with plenary power by the boards of directors of practically all railway companies to operate the railways as one national system during the war. In the national emergency, in which the closest possible coördination of the agencies of transportation with the several branches of the Federal Government was absolutely essential, the experiment of voluntary unification was not satisfactory, and on Jan. 1 1918, as a temporary war measure, the railways were taken over by the Government, to be operated by a director-general responsible to the President. Federal operation continued until March 1 1920, when the railways were returned to private operation under the terms of the Transportation Act of that year. That Act fundamentally amended the existing policy of national regulation of railways and extended the powers of the Interstate Commerce Commission. Principally because of the serious business depression of 1920-1, and the decline in the volume of railway traffic, the results of the first year of operation under the Transportation Act were disappointing. In the summer of 1921 the subject again was commanding national attention. A choice among three policies was then incumbent upon Congress: (1) to rely upon private ownership and operation under the principles of the Transportation Act (hereinafter described) to take care of the situation when business conditions became normal; (2) to make some compromise between a policy of private control and initiative and Government operation or ownership; and (3) completely to nationalize the railways.

Pre-War Conditions and Legislation.—The 1910 amendment to the original (1887) Act to regulate commerce (*see* 22.830) created the Commerce Court to act upon appeals from decisions of the Interstate Commerce Commission. The new court was intended to specialize in the technique of transportation and to expedite the determination of cases theretofore passed upon by Federal courts of general jurisdiction with crowded dockets containing cases of all kinds. In many of its early decisions the Commerce Court overruled the Interstate Commerce Commission and, because it appeared to limit the effectiveness of the Commission, the Court became unpopular. The public attitude toward railways at that time was unfriendly, and Congress responded to public pressure by abolishing the Commerce Court in 1913.

In response to an insistent public demand, growing out of the belief that the railways were being allowed to earn returns on fictitious capitalization, the Federal Valuation Act was passed in 1913. The Act required the Interstate Commerce Commission to determine the physical valuation of the railways individually, as of June 30 1914, and to cause records to be kept which would accurately

reflect all changes in property values after that date. Three bases were prescribed tentatively: (1) original cost to date, in the cases where the information could be obtained; (2) estimated cost of reproduction, new; and (3) estimated cost of reproduction, new, less depreciation. The work of determining values had been in progress since 1914, but no final figures were available in 1921 or expected until 1923 at earliest, although tentative valuations of a few properties had been made public.

Another piece of legislation, known as the Clayton Act, of 1914, contains a section which has an important bearing upon railways. The Act was intended to strengthen the so-called Anti-Trust Act and to prevent collusion between directors and officers of railways and directors and officers of manufacturing and other concerns dealing in railway equipment, coal and other supplies. It requires that contracts for supplies which will cost more than \$50,000 must be open to competitive bids invited by advertisements. A railway company is prohibited from having dealings in excess of \$50,000 per year with a concern having a director, officer or agent who is also a director, officer or agent of the railway. The Act was to be in force from 1916, but because of war conditions the effective date was postponed until Jan. 1 1921.

About 1906 a downward tendency began to be apparent in the rate of return on railway investment. This change restricted the flow of new capital into railway development—new lines and improvements of existing lines. The traditional policy of American railways had been to keep their facilities well ahead of the demands of growing traffic. In view of the fact that the volume of freight traffic doubles about every 12 years, and that the numbers of passengers carried one mile doubles about every 15 years, the need of such a policy is apparent. The practice of the conservative railways was to "plough in" a substantial part of their net income each year by making improvements out of income instead of issuing new securities. Such a policy, however, could not be continued with constantly diminishing net income. The downward tendency in the rate of return was caused in part by a hardening of the rate structure through a more inflexible policy of public regulation, in part by steadily increasing costs of wages and materials, and in part by the greater difficulty of finding means through economies and new operating methods of overcoming increasing costs. With declining net returns, and a general lack of confidence on the part of the public toward railways, railway securities lost their attraction, and investors sought other fields. The railways experienced much difficulty in obtaining new capital for the additional facilities required to keep their plants in step with traffic growth, and many of the weak lines reached such financial straits that they could not maintain their solvency. The cumulative effect of these tendencies reached the climax in 1913 when 42,000 m., or about one-sixth of the entire mileage of the country, was in the hands of receivers, and when less new mileage was built than in any year since the period of the Civil War.

Effects of the World War.—This was the situation when the effect of the World War was first felt by American railways. The orders from the Allies for munitions and other war supplies caused a sudden increase in freight tonnage. The additional revenues acted as a stay against financial distress, but the railways found their traffic-carrying capacity taxed to the full. Then came the added traffic burden when the United States entered the war in April 1917.

To meet the emergency the railways, through the American Railway Association, organized a railroad war board and delegated to its five members complete control over operation. The purpose was to coördinate management under private ownership and control so that the railways, during the war emergency, would merge their merely individual and competitive activities in the effort to produce the maximum of transportation efficiency. The board did much to increase the capacity of the railways through unified operation and common use of facilities, and during the first six months following voluntary unification, the heavily increased traffic was handled satisfactorily. But during the late autumn and early winter of 1917 acute traffic congestion occurred at the Atlantic seaboard ports, through which the greater part of the war supplies was exported, and the blockade extended back to the important inland industrial centres. The congestion was caused by several factors, among which two were outstanding. One has already been mentioned—the financial inability of the railways to keep up their former programmes of providing additional facilities in advance of traffic needs. The second was the lack of effective coördination between the railways and the several branches of the Government, each of which demanded priority of movement for its freight, thereby creating great confusion. The congestion and its interference with traffic, the perilous financial condition of the railways, the spirit of unrest among railway employees because of the greatly increased wage rates paid by manufacturing and ship-building plants, and the need of better coördination of all agencies essential to the successful prosecution of the war, led to the President's proclamation of Dec. 26 1917, taking over the railways to be operated by the Government from Jan. 1 1918. The Government could advance the funds required to provide the additional facilities urgently needed for war purposes; by paying a rental equivalent to pre-war net operating income it could prevent further bankruptcy of railway companies; by paying higher wages than the railway companies were able to pay, it could remove the cause of unrest among em-

employees; by making the railways a branch of the Government it could more effectively coordinate transportation with other Government activities; and by the complete temporary elimination of lines of corporate interest a more effective unification of all facilities and equipment would be possible.

Federal Control in the War.—The Federal Control Act of 1918 provided that the railways should be operated for the President by a director-general of railroads. Practically all of the railways were taken over, and were operated, with little change in the individual units, by Federal managers (in nearly all cases the former operating executive) reporting to regional directors, seven in all, who in turn reported to the director-general. The latter was assisted by staff-directors in charge of the several divisions—law, finance, purchasing, traffic, operation, labour, accounting, public service and capital expenditures. With few exceptions the entire organization, from the Federal managers to the regional and division directors, was made up of men carefully selected from the railway service. Political influence had no play in appointment. The Act provided that the railways should be returned to their owners for private operation within 21 months after the signing of the treaty of peace. The Government during the period of Federal control was required to keep up the usual standards of maintenance, so that the properties would be returned at the end of Federal control in as good condition and as complete in equipment as when taken. Failing to do this, the railway companies were to be compensated for the deficiencies. The annual rental was set as a sum equal to the average annual net operating income earned by the companies during the three years ended June 30 1917. The principles of unification and consolidation of facilities and equipment were carried much further by the director-general than by the Railroad War Board. Terminals and other facilities, and locomotives and cars, were used in common. Advertising, soliciting, off-line agencies, and other normal competitive activities were abolished. Traffic was routed by the most convenient lines, regardless of shippers' directions, or of the effect of diversions on the earnings of the individual units in the national system. The aim was to utilize every instrumentality of transportation to the highest degree of traffic-handling efficiency.

The results of Federal control during the year 1918 while the war was in progress were satisfactory in that they met the emergency. The traffic of that year, both in ton-miles and in passenger-miles, exceeded all previous records. What was more important, the coordination of railway management with other branches of the Government had the effect of producing the kind of transportation most necessary for war purposes. The congestion of the early winter of 1917 was quickly relieved. The heavy demands of troop movements were completely met. The loaded cars on hand at the seaboard were always a little ahead of the ocean-going tonnage capacity, and the railways, after May 1, kept up their part of the programme of moving export food supplies for the civilian population of the Allies. The insistent preference given to war traffic naturally entailed some curtailments in service for civilian population of the United States. These curtailments were patriotically accepted. A system of centralized control established priority for the various kinds of freight and controlled traffic at the source by requiring permits before freight would be accepted. Such permits were not issued unless transportation conditions at destination were such that the freight could be quickly unloaded. Manufacturers and dealers were asked to load cars with larger shipment units, or otherwise to conserve car space by changing methods of packing. One of the first acts of the director-general was to appoint a commission to make recommendations as to wage increases. The commission made its report in May and its recommendations were adopted and made retroactive to Jan. 1 1918. The increases in pay-roll expenditure were substantial. Coincident with the promulgation of the new wage scale, the director-general created the Board of Railway Wages and Working Conditions and later he appointed three Boards of Adjustment to pass upon disputes as to working rules and discipline. Both the wage and the adjustment boards were bi-partisan with equal representation from the officials, representing management, and from the execu-

tives of the labour organizations, representing the employees. During 1918 there were no strikes or other labour disturbances. The director-general was given almost autocratic authority to increase freight and passenger rates and other transportation charges or regulations. The Interstate Commerce Commission and the state commissions temporarily were shorn of power. An increase of 25% in freight rates and about 20% in passenger rates was made effective in June, a few days after the wage increases were announced. While in a general way it was hoped that the advances in rates, coupled with the expected economies in unified control, would offset the higher wage rates and other increases in operating costs, the net financial results were regarded as of secondary importance as compared with the increase of transportation capacity. The rate advances were insufficient to meet rising costs and the final result of the first year of Federal control, with no allowances for deficiencies in maintenance or depletion in stocks of materials and supplies, was a deficit of over \$200,000,000. In other words, the net operating income earned by the director-general was that much less than the rentals paid to the railway companies. This deficit, however, may properly be regarded as one item of the cost of carrying on the war. In view of the satisfactory transportation service, particularly during the summer of 1918 when the armies of the United States were at the height of their activities, and comparing the deficit with the expenditures of other branches of the Government, the cost was not great.

The second phase of Federal control was the period from the signing of the Armistice in Nov. 1918, until March 1 1920, when the roads were returned to private management. This post-war period of Federal control was not marked by results as satisfactory as those of 1918. It would have been much better if the period of Federal control had ended Dec. 31 1918. Immediately after the Armistice the moral factor of patriotism, which had been so effective during the first ten months of Federal control, almost entirely disappeared. As soon as the war was over the employees through their organizations began a campaign to hold and to extend further the concessions which had been made freely under the exigencies of war; the thoughts of the officers began to turn to their corporate and personal interests; and among a minority of the administration officials active steps were taken to bring about an indefinite extension of Federal control with the ultimate aim of nationalization. The public, however, had little patience with the director-general's proposal to Congress that Federal control should be extended five years, and the suggestion had little support outside of the labour organizations and the political forces aligned on the side of nationalization. Chambers of commerce, shippers' organizations, and the general public, in the natural reaction against perpetuating war-time governmental control of business, insisted that the railways should be returned to private control. This general attitude toward the subject, and the alarming deficits which were being added to that of 1918, influenced Congress to take active steps to restore the railways to their pre-war status, but great difficulty was experienced in agreeing upon a plan which would be satisfactory in detail to both the House and the Senate. While the hearings and the debates dragged throughout the year 1919, the transportation service suffered in efficiency and among the more radically inclined employees there were frequent and serious strikes. It was found necessary to grant further increases in wages and to enter into the so-called "national agreements" containing many burdensome and restrictive rules such as, for example, the abolition of piece-work in shops. Most of these national agreements were made almost on the eve of the return of the railways. They were drawn by the labour advisors to the director-general and were adopted over the protest of the railway operating officials. These national agreements were partially abrogated July 1 1921, by order of the Railway Labor Board created by the Transportation Act of 1920.

The final cost to the Government for the 26 months of Federal control was estimated by the director-general at a minimum of \$1,200,000,000. It seemed probable that it would be much

greater, as this estimate allowed only about \$300,000,000 for under-maintenance and for differences in the quantities of materials and supplies on hand at the beginning and at the end of Federal control.

A great deal of controversy arose over the question of relative maintenance during and prior to Federal control, but the differences hinge mainly upon the degree of under-maintenance. There can be no doubt that the condition of the properties was not so good at the end of Federal control as at its beginning, but the exact degree of deterioration cannot be determined as no inspection or survey was made when Federal control began. The records show conclusively that the normal rate of renewals of rails, ties and ballast was not kept up during Federal control, and the universal complaint of the railway executives that freight cars were not maintained at normal standards is supported by the opinions of experts. On the whole, the conditions of locomotives did not suffer, but less than the normal amount of work was done on passenger cars. Bridges and buildings suffered because of neglect in painting, but on the other hand many improvements were made in shops and in engine-house facilities. Whatever may be the degree of under-maintenance it should be remembered that it was impracticable during the greater part of the period of Federal control to obtain the necessary amount of materials and full forces of men. These difficulties were partly removed in 1919, but in that year the serious decline in traffic and in earnings made it inexpedient, in the judgment of the director-general, to attempt to make up the deficiencies. A proviso in the contract between him and the railway companies gave the director-general the option of measuring his maintenance obligations by the amounts actually spent by each company during the three years prior to Federal control, these amounts to be properly equated to allow for increases in the cost of wages and materials, and he chose to limit the expenditures so as to keep them within that obligation, leaving the accounting and the settlement to be worked out after the termination of Federal control. Instructions were issued, however, that nothing essential to safety in operation was to be left undone. An inspection of the amounts spent for maintenance, particularly for maintenance of equipment, indicates that even with a generous allowance for the higher wage rates and material costs, the director-general expended amounts which were equivalent to those spent by the railway companies prior to Federal control. This method of comparison, however, takes no account of the important factor of relative efficiency of labour. During 1918, when so many railway men were drafted or had volunteered for military service, the percentage of inexperienced employees was abnormally large, and during 1919 the general lowering of the morale and the frequent strikes of men engaged in maintenance work led to a much lower degree of efficiency. The director-general held to the view that the Federal Control Act and the standard contract based upon it did not require him to take account of relative efficiency—that his obligation ended when he had expended an amount equivalent, when properly equated for the higher wage rates, to that spent in the test period. The railway companies on the other hand insisted that if in the test period 100 man-hours cost \$30 and produced 20 units of work, and if during the year 1919 the same number of man-hours cost \$60 but produced, say, 8 units of work instead of 20, the spirit of the Act is not followed unless the director-general spent enough in excess of \$60 to produce 20 units of work. This is the real point of difference. In the settlements made since the termination of Federal control this issue has been avoided by a policy of compromise and by lump-sum adjustments in which maintenance is but one factor, but it is probable that some of the companies which have large claims for under-maintenance pending may prefer to take the case to the courts for decision.

Too much emphasis, however, should not be placed upon the financial results of Federal control. Deficits might have been reduced or entirely avoided, and a surplus laid aside for the settlement of claims, if the 1918 advances in rates had been greater or if supplementary advances had been made in 1919 to take

care of the further wage increases granted in that year. The attitude of the administration was that it made little difference whether the higher operating costs were met indirectly through taxes or were directly collected from shippers and passengers in higher rates. As between the two alternatives the administration chose the first on the ground that another rate advance would have a serious effect upon the already much disturbed business conditions, and would be made the excuse for further profiteering. Speaking in general terms it may be said that the policy of the Government in taking the railways and operating them while the war was in progress was vindicated by the favourable operating results which flowed from a centralized and unified control. On the other hand it may be said that the experience of the post-war period of Federal control was not such as to justify a peace-time policy of Government operation or ownership under a democratic form of Government which relies upon the free play of the forces of competition. The unfavourable reaction of public opinion may be traced primarily to the elimination of competition in service. The railways were finally returned in response to an overwhelming public demand that private operation be restored, and almost immediately after its restoration, the desire for competitive service caused the abandonment of practically all the innovations of unification under Government control and operation.

The Transportation (Esch-Cummins) Act of 1920.—The conditions under which the railways were returned, and the policies of public regulation as they existed in 1921 were fixed by the Transportation Act of Feb. 1920, amending the original (1887) Act to Regulate Commerce. Besides providing for the restoration of operating control to the owning companies the Act provided that during the first six months, the so-called transition period, while railway rates and wages were in process of further upward revision, the Government would continue the guaranteed rentals paid during the period of Federal control. A Railroad Labor Board was created to pass upon wage matters, and made substantial increases in July 1920. The Interstate Commerce Commission was instructed to establish rates so that on the basis of current costs and under honest, economical and efficient operation, they would yield net operating income sufficient to pay a fair rate of return upon the value of the railway properties held for and used in the service of transportation. For the first two years the fair rate of return was set at 5½%, with an extra 0.5% (6% in all) to make provision for improvements chargeable to capital accounts. This mandate to the Commission, however, applied to the railways as a whole, or as a whole in territorial groups. For the purposes of the Act the Commission later divided the railways into three general groups, the eastern, the western and the southern. The mandate did not apply to individual roads in a group. Obviously a rate scale which will yield 6% to all of the railways in a group will yield more than 6% to some and less than 6% to others. No relief is provided for the railways which earn less than 6%, but when more than 6% is earned by a railway, the excess is to be evenly divided with the Government. The railway is to hold its proportion of such excess in a reserve fund and the one-half which goes to the Government is to be held by it as a general railroad contingent fund to be administered by the Commission in assisting the weak roads by loans. The reserve fund created by a railway from its excess earnings is to be held for interest charges or dividends in lean years, but whenever that fund is more than 5% of its property value, the excess over 5% may be used for any lawful purpose.

The problem of the weak railway has been for many years the principal obstacle in the path of a satisfactory solution of the railway question. In the determination of competitive rates, for example, a scale which will give a reasonable return upon the value of a weak railway will give too much to the strong railway. Conversely, when the scale gives a reasonable return, but not more, to the strong railway, the weak one cannot live. In practice the regulating authorities have been forced to adopt a middle ground with, perhaps, a tendency to lean more toward preventing an unreasonably high return to the strong than an unreasonably low return to the weak. An attempt has been made to meet this problem in the Transportation Act which provides for the ultimate elimination of the weak railways by consolidation with the strong. The Commission is ordered to prepare and adopt a plan for the consolidation of railway properties into a limited number of systems. Such a plan is to preserve a reasonable degree of competition and to maintain so far as practicable the existing routes and channels of trade and commerce. The desiderata are that the several systems shall be so arranged that the cost of transportation as between competing systems, and as related to the values of the properties, shall be approximately the same, so that these systems can employ uniform rates in the movement of competitive traffic, and can earn, under honest and efficient management, substantially the same rate of return upon the value of their respective properties. The Commission in June 1921 was engaged upon the formulation of such a plan, but as the Act pro-

vided no way in which its recommendations might be enforced when objections were raised against its terms, there seemed likely to be long-drawn-out controversy and additional legislation before an ideal scheme of consolidation into a small number of systems of fairly equal financial strength would be made effective. The new Act enlarges the powers of the Commission over financial management and requires it to exercise a general supervision over all new issues of securities. The Railway Labour Board (consisting of nine members divided equally among representatives of management, labour and the public) is empowered to fix wages and working rules.

The foregoing outline mentions most of the important new features in the 1920 legislation amending the original Act to Regulate Commerce and the amendments up to 1920. The fundamental provisions of the original Act remained in force in 1921 and had been extended or otherwise strengthened. Briefly, the Commission is required to see that rates and charges are just and reasonable; to prescribe the rules under which rates may become effective; to prevent unfair discriminations between shippers, carriers or localities; to prevent, except when specifically authorized, the charging of a higher rate for a short haul than for a longer haul over the same route in the same direction; to prevent the pooling of freight or earnings; to require complete reports from carriers in prescribed form; and to prescribe and enforce uniform rules for accounting and for compilation of statistics of operation.

In addition to the Federal legislation just described, each state exercises its powers of regulating intrastate traffic and of exercising what may be termed "police powers" over railway management and service within its own borders. The line between Federal and State regulation is not clearly drawn, and controversies between the two authorities have been frequent. On the whole, the tendency of court decisions during the decade 1910-20 was toward according greater powers to the Federal commission and less power to the State commissions, as it has been shown that the states, when exercising control over intrastate rates and service, may indirectly discriminate against interstate traffic and service.

In addition to the changes in the Act to regulate commerce, new legislation was enacted during the decade which strengthened and extended the laws pertaining to safety appliances and accident prevention. These laws govern certain features of design and maintenance of locomotives and cars and of operating methods in train service. For example, the use of high-power headlights has been made compulsory, and the requirements as to boiler inspection and the general condition of locomotives have been made more rigid. The scope of the laws governing maximum hours of service was enlarged. The eight-hour basic day, prescribed for train service employees by the Adamson Act, passed by Congress in 1916, was extended during the period of Federal control to apply to practically all classes of railroad employees.

Statistics.—The salient features of mileage, investment, income and transportation production in ton-miles and passenger-miles, are shown in Table I. compiled by the Bureau of Railway Economics, Washington, D.C., under date of March 21 1921. The figures apply only to Class I. railways, i.e. those which have operating revenues in excess of \$1,000,000 per year. These railways comprise about 92% of the total main-track m., about 95% of the total capitalization, and they earn about 97% of the total operating revenues.

In interpreting the figures in Table I. it is necessary to bear in mind that the results of 1917-20 were very much affected by war conditions and by Federal operation of railways from Jan. 1 1918 until March 1 1920. The period was one of abnormally high operating expenses and of greatly diminished net income, notwithstanding the large operating revenues. Obviously a continuation of the low income of 1919 and 1920 would cause universal railway bankruptcy. The aim of the Transportation Act of 1920 was to restore the pre-war earning power, to enable the railways to give better service, and to provide revenues which with reestablished credit would permit expansion and improvements in facilities and equipment.

Details for 1917.—Instead of figures for a later year, those of 1917 are selected to give an indication of the normal characteristics—financial, operating and public service of American railways.

On Dec. 31 1917 the total route mileage of railways of all classes was 253,626 miles. This was equivalent to 8.53 m. of railway for each 100 sq. m. of territory, or 24.39 m. for each 10,000 inhabitants. The relation of route mileage to track mileage (for Class I. roads only) is shown in Table II.:

TABLE II. ROUTE AND TRACK MILEAGE. CLASS I. ROADS, DEC. 31 1917

Item	Miles	Per cent. of route miles
First main track (route m.)	232,697	100.0
Second main track	29,913	12.9
Third main track	2,775	1.2
All other main tracks	2,190	.9
Yard tracks and sidings	101,108	43.5
Total all tracks	368,683	158.5

The total route mileage of railways of all classes in 1917 was owned by 1,874 separate companies. Of these, 186 were railways of Class I.

with route mileage as shown in Table II., made up of 178,707 m. owned and 33,990 route m. operated under lease or similar arrangement. The average route mileage operated per Class I. road was 1,251 miles. For railways of Classes II. (those with operating revenue \$100,000 to \$1,000,000 per year) and III. (those with operating revenues below \$100,000 per year, including switching and terminal railways) the average was 44 miles. The greater part of the mileage owned by the large number of small companies is leased to and operated by Class I. roads.

Finances.—The total railway capital outstanding Dec. 31 1917 was \$21,249,357,241. This, however, included certain duplications in securities of one company held by another company and used by the second company as the basis for additional securities. Eliminating the intercorporate holdings and other duplications, the net capitalization on that date was \$16,401,786,017, or \$66,699 per route mile. Of this net capitalization, \$39,930 per route m., or 59.9% of the total, was in capital stock, and \$26,769, or 40.1% of the total, was in bonds or other forms of funded debt. In that year the average dividend paid on all stock was 4.24%, but no dividends whatever were paid on 36.7% of the stock. The average dividend rate on the dividend paying stock alone was 6.81 per cent. The average rate of interest paid upon funded debt may be estimated as about 4 per cent. The number of stockholders was approximately 670,000 and the number of bondholders about 300,000.

Table III. gives the income account of all railways considered as one system, including switching and terminal companies, for the year ended Dec. 31 1917:—

TABLE III. INCOME ACCOUNT, ALL RAILWAYS, 1917

Railway operating revenues	\$4,178,784,652
Railway operating expenses	2,956,770,809
Net revenue from railway operations	1,222,013,843
Railway tax accruals	227,301,093
Uncollectable railway revenues	711,879
Railway operating income	994,006,871
Equipment and joint facility rents (net deduction)	26,573,773
Net railway operating income	967,427,098
Other income (non-operating)	101,808,148
Gross income	1,069,235,246
Net interest charges	475,646,748
Other deductions from gross income	24,371,700
Net income	569,216,798
Net dividends (including dividend appropriations from surplus)	293,291,808
Income above dividends	275,924,990

Of the total operating revenues about 70% came from the transportation of freight and about 25% from passenger-train service including mail and express. The remaining 5% was miscellaneous operating revenue. The operating expenses were divided as follows: maintenance of way and structures, 15.6%; maintenance of equipment, 24.2%; traffic (solicitation, advertising, etc.), 2.3%; transportation (operation of stations, yards, terminals and trains), 33.6%; general expenses, 3.4%; and miscellaneous, 0.9%.

On Dec. 31 1917 the equipment owned by railways of all classes was as follows:—

Steam locomotives	63,699
Other locomotives	371
Freight train cars	2,408,518
Passenger train cars	55,939
Company service cars	103,916
Steamboats and tugboats	411
Barges, car-floats and canal-boats	1,868
Other floating equipment	263

The item "other locomotives" is made up almost entirely of electric locomotives. "Freight train cars" do not include private freight cars (numbering about 80,000) owned by meat-packers, oil companies and similar industrial concerns. "Passenger train cars" do not include parlor and sleeping cars owned by the Pullman Co., of which there were 7,706. "Company service cars" include ballast cars, construction cars, wrecking cranes, etc.

The average number of employees during the year 1917 for all railways was 1,833,732. For Class I. railways only, the number was 1,732,876, divided as follows:—

Class	Number	Percentage
General and divisional officers	18,446	1.1
Clerks, messengers and attendants	192,569	11.1
Maintenance of way employees	448,720	25.9
Maintenance of equipment employees	388,837	22.4
Traffic department employees	8,333	.5
Dispatchers and telegraphers	67,455	3.9
Station employees	132,562	7.6
Yard and engine-house employees	183,877	10.6
Train-service employees	226,936	13.1
All other employees	68,141	3.8
Total	1,732,876	100.0

RAILWAYS

TABLE I. MILEAGE, INVESTMENT, REVENUES, EXPENSES, 1911-20, INCLUSIVE, OF CLASS I. RAILWAYS

	Fiscal Years ended June 30.					Calendar Years ended December 31.				
	1911	1913	1914	1915	1916	1916	1917	1918	1919	1920
Miles of track operated — main track	244,300-77	254,821-20	259,139-53	262,424-88	264,920-40	265,802-97	267,574-12	269,174-54	270,856-62	
Property investment — Class I. roads and their non-operating subsidiaries (investment in road & equipment, exclusive of materials and supplies)	\$14,246,167,475	\$15,284,763,489	\$15,842,127,273	\$16,257,146,632	\$16,688,440,056	\$16,884,440,038	\$17,762,159,127	\$18,213,629,613	\$18,474,197,914	
Total operating revenues	2,752,497,297	3,108,361,215	3,031,326,963	2,871,563,047	3,381,597,866	3,596,865,766	4,014,142,748	4,880,953,486	5,143,589,998	\$6,171,493,301
Total operating expenses	1,902,994,333	2,173,463,563	2,203,423,812	2,021,160,614	2,210,892,786	2,357,308,412	2,820,325,124	3,982,068,197	4,398,408,414	5,768,720,013
Operating ratio—%	69-14	69-92	72-69	70-39	65-38	65-54	70-43	81-58	85-51	93-47

*Not available in 1921. ^a Total operating revenues for 1920 includes approximately \$5,000,000 of back mail pay collected in 1920 but applicable to services rendered in 1918 and 1919. ^b Computed on investment of 1919.

NOTE: Net Railway operating income as shown above for 1918, 1919, and 1920 represents the actual earnings from operation of the Class I. railways. The "standard return" for these roads (i.e. the net operating income after collecting rental from the U.S. Government) amounted to approximately \$898,500,309 for the years 1918 and 1919, and for 1920 amounted to approximately \$825,000,000, taking into account two months of Government operation, six months of Government guarantee and four months of private operation.

RAILWAY STATIONS

The subsequent application, during Federal control, of the eight-hour day (instead of the former basis of 10 hours for a large proportion of employees) to practically all of the classified employees had the effect of increasing the number of men required to do a given number of hours of work. At the end of Federal control the total was about 2,000,000 employees, not including conductors and porters on Pullman cars employed by the Pullman Company.

Construction and Equipment.—The tendency in the decade 1910-20 was toward the use of heavier rails. On heavy traffic lines, using the most powerful locomotives, rails weighing 100 lb. per yd. were being replaced by rails weighing 105 to 110 lb. On other lines which had used 85-lb. rails, the tendency was toward 100-lb. rails. Greater attention was paid to the relative proportions of the chemical elements in steel and the mills were turning out rails of improved design and of greater strength and wearing qualities. The marked development in the weight of locomotives and cars placed much greater strains on the track superstructure and roadbed. In 1921 American Railway Engineering Association standards for depth of ballast had not been changed recently, but some of the heavy traffic roads were increasing the amount of ballast from 12 in. to 20 in. below the ties. The experiments in the use of steel and concrete ties as substitutes for wood ties (sleepers) had not given satisfactory results under the heavy axle loads of American equipment, and there was little inclination to use substitutes for wood, notwithstanding the marked depletion of the lumber supply. There was, however, a more general use of preservatives in treating ties chemically to strengthen their resistance to decay, and a more general use of tie plates, between the base of the rail and the top of the tie, to lessen the mechanical wear on the tie. The screw spike, in place of the out spike, for fastening the rails to the ties, was having greater use, but was not common. The heavier axle loads required a general strengthening of bridges, and throughout the whole field of maintenance engineering the adoption of higher standards during the decade was noticeable.

There was a marked development in the art of signalling. The use of electrically controlled automatic block signals is distinctively an American characteristic. There was a steady tendency to substitute automatic block signals for the older type which are manually operated. In 1911 there were about 29,000 m. of main track equipped with automatic block signals. In 1920 the mileage so equipped was over 61,000 miles. The use of these modern signals not only increases the safety of train operation but it also has the effect of increasing the capacity per mile. In the interest of safety there was a popular demand that block signalling should be made compulsory by law, and the Interstate Commerce Commission has repeatedly recommended legislation which would require the railways to adopt an annual programme under which all railways would eventually be completely equipped with block signals. Congress, however, had not by Jan. 1921 legislated on the subject, mainly because of the difficulty of formulating a plan which would fit the varying needs of roads with differing degrees of traffic density, and because of the heavy financial burden which compulsory block signalling would place upon the railways. There was also a widespread demand for the adoption of a device of some kind which would automatically stop the train when the engineer failed to observe the signal and ran past one which was in the stop position, but Congress appears to take the position that it is more important first to extend the installation of block signals before insisting upon the expensive supplementary safeguard of the automatic stop.

In 1910 the average weight of all locomotives, exclusive of tender, was about 73 short tons. In 1920 it was about 90 short tons. The tendency was steadily toward the use of more powerful locomotives and the retirement of the lighter types. The locomotives ordered in 1920 weigh from 100 to 200 tons, with a few of the Mallet compound type of much greater weight. The use of steel passenger cars calls for larger locomotives in that class of service, and the American policy, consistently followed for years, of increasing the freight-train load, required the use of more powerful locomotives in freight service. The average freight-train load, in tons of freight, grew from less than 400 tons in 1910 to more than 700 tons in 1920. Not all of this increase is to be attributed to the heavier locomotive. Reductions in grades and curvature have made heavier trains possible. There was also a general improvement in the technique of tonnage ratings for locomotives. In addition there was a more general use of the superheater on locomotives. This device reduced the loss in steam pressure between the boiler and the cylinder and increased the drawbar pull. The use of automatic stokers on the most modern type of freight locomotive removed one limiting point: the capacity of the fireman in shovelling coal into the fire box. A recent device for increasing locomotive capacity is known as the "booster." It is a small auxiliary engine geared to the trailing axle (on locomotives which have a pair of wheels not connected with the main drivers) and may be used in starting the train or in giving an extra drawbar pull on the limiting grades.

While not so marked as in the case of the locomotive, there has been a steady increase in the weight and capacity of freight cars, particularly in those designed to carry coal, ore, or steel or iron products. The standard coal car of 1921 had a capacity of 100,000 lb., and in some cases cars of double that capacity were used locally on the owning road in coal or ore traffic. There was no appreciable

increase in the capacity of box cars as the commercial standards do not call for larger units than 60,000 to 80,000 lb. per car.

Reference has already been made to the more general use of steel in passenger-car construction. Virtually no new wooden cars were built for passenger service after 1915. On Jan. 1 1911 the passenger-train equipment consisted of 50,201 wooden cars, 1,636 of steel underframe construction, and 3,133 of all-steel construction. On Jan. 1 1919 the numbers were: wood, 36,810; steel underframe, 8,805; all-steel, 18,652. The use of the old wooden cars was generally confined to local trains and branch lines.

Accidents.—A comparison of the latest available complete accident statistics (in *Bulletin 74, Interstate Commerce Commission*, published in Nov. 1920) with the statistics for 1907 and 1908 (see 22,832) indicate a gratifying improvement. The casualties in 1919 were less than those of 1907 or 1908, notwithstanding the fact that the volume of traffic in 1919 was nearly double that of 1907. The improvement may be attributed to several factors, but it is difficult to list them in the order of their importance as the influence of any one factor cannot be measured separately. Among them are (1) higher standards of construction and maintenance of way, structures and equipment; (2) enforcement of laws relating to safety appliances, boiler inspection, and hours of service; (3) extension of block signalling; (4) other improvements in operating methods; (5) the psychological effect of the "Safety First" movement, begun about 1910 (a nation-wide movement to interest railway employees in accident prevention); and (6) the publication of results of investigations made by the Interstate Commerce Commission in specific accidents. The data contained in the appended table were taken from *Bulletin 74*.

CASUALTIES TO PERSONS IN TRAIN ACCIDENTS AND TRAIN SERVICE ACCIDENTS

Item	1919		1918		1917	
	Killed	Injured	Killed	Injured	Killed	Injured
Passengers:—						
In train accidents	110	4,549	286	4,655	131	4,460
In train service accidents	191	3,598	233	3,427	212	3,914
Total passengers	301	8,147	519	8,082	343	8,374
Employees on duty:—						
In train accidents	359	2,955	547	4,179	439	4,214
In train service accidents	1,334	33,325	2,212	42,782	2,177	48,022
Total employees on duty	1,693	36,280	2,759	46,961	2,616	52,236
Employees not on duty:—Total	66	321	169	595	165	544
Other persons, not trespassing:—						
In train accidents	9	61	117	433	109	473

Grand Total	6,495	52,601	8,697	64,144	9,567	70,970

*Includes persons struck by trains at highway crossings.

The analysis of train accidents in 1919 shows that the total number was 25,596, divided as follows:—collisions, 6,904; derailments, 15,897; locomotive accidents, 674; and miscellaneous, 2,121. These figures include all train accidents, with and without personal injury. Collisions caused the death of 238 persons and the injury of 3,931. The casualties in derailments were 175 deaths and 2,979 injuries. The casualties in locomotive and miscellaneous accidents were relatively few. (W. J. C.)

RAILWAY STATIONS.—The improvements made during the decade 1910-20, especially in the United States, in the construction and operation of railway passenger stations, may be said to have revolutionized railway terminal construction; and the newer stations, of which the Grand Central terminal in New York is the outstanding example, demonstrated even after a short period of operation their superiority from practically every point of view. The substitution of electricity for steam as a motive power was the basic factor in the newer methods of construction. As long as steam was used little could be done to mitigate the noise or noxious gases that made the old-fashioned railway yard a public nuisance. It was virtually necessary to operate these yards on the surface where the products of combustion could make a free escape to the open air. In any confined space steam operation is not only dangerous, owing to the tendency of smoke to obscure the signals, but unpleasant for pas-

sengers. The use of electricity eliminates the noxious gases and reduces the noise of the locomotive. An electrified yard can be depressed and completely covered over. This permits the reclamation of streets and valuable areas hitherto obstructed by tracks, with the result that what was formerly a railway yard filled with steam and smoke can be utilized for public and private buildings of the finest character.

In Europe, the completion of the passenger station at Leipzig (1915) was practically the only terminal improvement that was not interrupted by the World War, although the Gare St. Lazare in Paris was somewhat enlarged, and in London, Waterloo station was partly reconstructed and a number of tracks equipped for electric operation. The Leipzig station was under construction from 1907 to 1915, and cost £6,500,000, of which, following the German practice, £2,900,000 was borne by Saxony, £2,550,000 by Prussia, £810,000 by the city of Leipzig and £240,000 by the Imperial Post Office Department. The main building has a frontage of 984 ft. and occupies an area of 172,000 sq. feet. The train shed has a high roof of steel and glass, built in the form of six arches; it is 785 ft. long, with an area of 710,500 sq. ft., and covers 26 tracks. The station serves as a junction for the passenger traffic of Magdeburg, Thuringia and Dresden, and the larger part of the traffic between Prussia and Saxony passes through it.

At the close of the decade the Leipzig station was the largest, though not the busiest, station in Europe. It was smaller than the Grand Central and Pennsylvania stations in New York, and was in 1920 handling considerably less than half as much traffic as the Gare St. Lazare, the busiest station in the world. It was said in 1916 that the number of persons passing through the St. Lazare in a single month equalled the total number of soldiers fighting on all fronts. Plans were then undertaken to electrify the suburban traffic, which is very heavy, and to depress the suburban tracks to a level beneath the steam trains. Even without these increased facilities, the station furnished accommodations for 200,000 to 250,000 passengers a day, a record, however, very nearly equalled in London by Liverpool St. station. Both the Gare St. Lazare and Liverpool St. station handled on busy days twice as much traffic as the South station in Boston, the busiest American station.

TABLE I. Largest Railway Stations.

Station	Ac.	No. of Tracks	Trains per day	Passengers per day
Grand Central, N.Y.	80	67	600	110,000
Pennsylvania, N.Y.	28	21	500	75,000
Leipzig	20	26	400	—
St. Lazare, Paris	12	31	1,700	200,000
Liverpool St., London	10	20	1,500	175,000
Waterloo, London	9	18	1,100	100,000
South, Boston	10	28	1,000	125,000
Kansas City	18	18	400	65,000
Northwestern, Chicago	8	16	450	70,000

Outside of Europe and North America two important stations were erected, one in Argentina and one in Japan. The Retiro station of the Central Argentine railway at Buenos Aires, said to be the finest station in South America, was opened in the latter part of 1915. The terminal, including buildings, train sheds and approaches, occupies 744,000 sq. ft., and in point of size and design compares with any of the newer stations elsewhere. Much of its equipment was supplied by English contractors. The Central Railway station in Tokyo, completed in 1915, was erected at the very small cost of £270,000, although it is built on a scale which in the West would cost 10 or 20 times as much. The explanation lies in the extremely low price paid for Japanese labour, 10¢ (\$.20) a day (of 10 to 12 hours) for common labourers, and £5 a month for carpenters and masons. Estimated in days' labour, the cost was 730,000 labourer-days. The main building is of brick and granite, 1,104 ft. long, 66 to 132 ft. wide and 54 ft. high, with a dome (152 ft.) at either end. The terminal took the place of three stations which formerly served the three main-line Government railways.

In the United States and Canada a constantly increasing railway traffic made necessary the construction of a large num-

ber of new stations. Terminals that had been erected with the expectation that they would serve their purpose for 50 years or longer became inadequate in less than half that time. The result was that the newer stations were built on what would otherwise be considered too extravagant a scale. The designers were looking to the future.

One distinctively American contribution to the advance of terminal architecture was the invention of an improved roof to take the place of the great arched train shed, once considered the most necessary adjunct of a railway station. Cold in winter and hot in summer, these sheds were expensive to build and expensive to maintain. Even at the height of their popularity there were some designers who preferred the umbrella or butterfly types of shed, consisting of a series of low arches which, viewed in cross section, suggest the names by which they are known. After 1905 the Bush type of shed began to supersede all others, especially where steam was still tolerated in the terminal area. This shed was the invention of Lincoln Bush, who made the first installation at the Hoboken terminal of the Delaware, Lackawanna & Western railway, of which he was chief engineer. The Bush shed is similar to the butterfly and umbrella sheds; it differs principally in that it affords a continuous roof except for an overhead slot above the centre of each track for the escape of steam and gases from locomotives. A shed of this pattern affords protection from the weather, is free from smoke and dirt, and costs about one-half as much as the large arched shed. Within ten years after its invention the Bush shed had been adopted in 11 American and Canadian terminals, notably the Michigan Central station at Detroit, the Northwestern at Chicago, the Grand Trunk at Ottawa and the Canadian Pacific at Montreal. In England there was developed a somewhat different type known as the "ridge and furrow," of which the Snow Hill station of the Great Western railway at Birmingham, reconstructed in 1914, furnishes an example. The Snow Hill train shed consists of a series of transverse girders (275 ft. long with four supporting columns) spanning the entire width of the station. The best results, however, can be attained only where the smoke and dirt of steam operation are eliminated altogether. The problem of the train shed was most completely solved in the Grand Central terminal, New York, where electricity was adopted as a motive power. Here the "sheds" closely resemble the stations on a subway or underground railway.

Less successful in this respect, though of first-rate importance among the new stations of the period, was the Pennsylvania station in New York. Being of the so-called through-station type, this station is essentially a monumental bridge over the tracks, which traverse Manhattan Island in tunnels under the city. The main building was designed after the Roman Doric style of architecture and occupies two complete blocks (8 ac.), on Seventh Avenue from 31st to 33rd Streets. The general waiting-room is 277 ft. by 103 ft., with a height of 150 feet. The train yard or shed (340 ft. by 210 ft.) is an "undisguised example of modern engineering in glass and iron," and suggests somewhat the old-fashioned train shed. The station was built primarily to provide the Pennsylvania railway with a terminus in New York (before 1910 the terminus was in Jersey City), and the construction of the river tunnels, which were necessary to make a connexion with Manhattan Island, was an engineering feat of considerable magnitude. The improvement extends from Manhattan Transfer, 1 m. east of Newark (about 7½ m. from the terminal), to a connexion with the Long Island railroad at Woodside, L.I., which also used the Pennsylvania station as a terminus. At Manhattan Transfer incoming Pennsylvania trains change to electric operation and are hauled by electric locomotive, operating with a direct current of 600 volts from a third rail. At the New Jersey shore they descend into one of the two approach tunnels and proceed under the Hudson river and New York to the Pennsylvania station. As soon as empty they leave the station to the east, still travelling underground in one of four tunnels which pass under eastern Manhattan and the East river to Long

RAILWAY STATIONS

Island, where they emerge not far from the railway yards. The terminal was completed in 1910 at a cost of \$115,000,000.

The Grand Central terminal, undoubtedly the most successful modern terminal of any type, was begun in 1903 and opened to the public in 1912. The primary purpose was to provide not only the necessary traffic facilities for an enormous number of passengers—ultimately expected to reach at least 250,000 a day—but to ensure pleasant and comfortable accommodations for every passenger, even at times when the crowds were heaviest. Subsequent development of the terminal area has made the Grand Central terminal not merely a railway station but a civic "center" of impressive beauty and utility. A railway station should form a harmonious unit in the architectural development of the city, but the designers of the Grand Central terminal accomplished something more than that: they actually transformed the architectural aspect of a very considerable section of New York. They achieved this result partly by setting a high standard themselves and partly by causing practically every property owner and builder within that section to measure up to it. The achievement was the more remarkable in that the entire project was conceived and carried out by the New York Central lines, a private corporation, without assistance of the city or state. The extraordinary architectural and economic success of this terminal was largely due to the intensive utilization of areas immediately adjoining the tracks and even over the tracks themselves—areas that were formerly incapable of being used or were suitable only for cheap dwellings or certain kinds of factories. Early plans did not contemplate buildings of a greater height than six stories in the immediate terminal area, but as soon as it was evident that noise, smoke and dirt had been successfully eliminated there arose a demand for hotels and office and apartment buildings of 25 and even 30 stories. This development was favoured by the fact that in constructing the terminal the engineers were able to restore to public use a number of streets that had hitherto been entirely done away with or existed only as foot bridges. The underground areas, yards, etc., occupy about 80 ac., which above the surface are covered with a great variety of buildings. It was not long before the enormous expenditure on the terminal, about \$150,000,000, came to be economically justified by reason of the high return obtained from the lease of the space over the yards, etc., for building purposes, the so-called "air rights." In 1920 this return was sufficient to meet the fixed charges on the entire investment. The problem of building the station was extraordinarily complicated, and the closest coördination between the operating and engineering departments was necessary to carry out the new construction while tearing down the old station and at the same time keeping in operation some 800 trains a day, including those run for construction purposes. There were excavated 3,250,000 cub. yds. of material (more than two-thirds of which was solid rock), and in the construction there were used about 1,000,000 bar. of cement; and all this work was performed without interruption to the service rendered the public. The architects, Reed & Stem and Warren & Wetmore, adopted a modified Doric style. The "head house," or station proper, is of monumental proportions and the façade (on 42nd St.) consists of three great portals designed to carry out the idea of a gateway. The exterior is granite and Indiana limestone. The main concourse, with a length of 275 ft. and a width of 120 ft., can accommodate 30,000 people at one time. Its great height (125 ft.) gives it an effect of unusual spaciousness. From the concourse the passenger walks directly out on the same level to the "express" platforms. In winter the main concourse is kept warm by indirect heating, and the station platforms are protected against inclement weather so that even on the coldest days the passenger can board his train in comfort. The tracks occupy two levels. The express level is 20 ft. below the level of the street (Park Ave.) and occupies 45.4 ac.; the suburban level is 44 ft. below the street and occupies 32.8 acres. There are 42 tracks on the upper level and 25 on the lower; a special waiting-room (the suburban concourse) gives access to the latter. Leading from the main concourse are connexions

with the incoming waiting-room (or station), the Commodore and Biltmore Hotels, the Yale Club, the Vanderbilt Concourse office building and various other buildings. The incoming waiting-room, located beneath the Biltmore Hotel, has separate passage-ways of its own leading to the concourse, the subways, the street, etc., so that passengers arriving in the terminal do not interfere with the flow of people to trains. The use of ramps, or inclined passage-ways, instead of stairways, facilitates the movement of passengers and lessens the danger of accident. Nearby hotels include the Belmont and Chatham.

A vital necessity in designing the Grand Central terminal was a signalling system for each level that could be operated by a director who could not possibly see the train movements which he controlled. Interlocking machinery, which in its simplest form is locking mechanism designed to control the signals so that they will automatically indicate the position in which the switch is set, was originated in England about 1856, but its use did not become general for many years. To operate the complicated network of trackage in a modern terminal requires interlocking machinery of an extremely elaborate character; the mechanism must safely control traffic and permit train movements with the greatest possible despatch. In the Grand Central terminal the interlocking machinery is of the all-electric type. Each track level is controlled by a director who is guided by a diagram on which the movement of trains is indicated by small electric lights. The largest of the signal machines is operated by 400 levers, each of which moves electrically a switch or signal, and to each 40 levers is assigned a man working under the instruction of the train director. The machinery is as nearly automatic as possible. Alternating-current track circuits are used to prevent the operation of switches while trains are moving over them and to indicate the presence of trains in proximity to danger zones. These circuits also operate electric locks which automatically hold the levers so that they cannot be moved except when the track is clear. Alternating current is used because of the 660-volt direct-current circuit employed for electric motive power. There are five main interlocking stations. The procedure in the case of an incoming train is as follows: At Harmon (3.3 m.) the steam locomotive is detached and an electric locomotive substituted. From Mott Haven Junction (5.3 m.) the train is announced to the director by telegraph or loud-speaking telephone (a telephone instrument with a horn similar to that of a gramophone instead of a receiver). After the train has passed 72d St. the director can trace its further progress by means of the electric buttons on his diagram, and he then decides upon which track to receive the train and gives his order to the levermen accordingly. When the incoming track is determined an announcement is made by means of the teleautograph to various parts of the terminal. This instrument notifies the attendant at the incoming bulletin board and, in the case of through trains, serves to summon the station porters.

The Grand Central terminal was built by the New York Central lines under the direct supervision of W. H. Newman, then chairman of the board of directors. The terminal is owned 60% by the New York Central lines and 40% by the New York, New Haven & Hartford railway, and is used by both railways under a detailed operating agreement. In 1920 the traffic capacity of the station was far from being reached, yet more than 110,000 passengers used the station, arriving and departing on some 600 trains daily. Besides these there were every day from 50,000 to 100,000 people who passed in and out of the station without using the trains. Of the daily traffic about 65,000 were suburban passengers, and this kind of traffic was steadily increasing. From 1903, when the construction was begun, to 1920 the total passenger traffic very nearly trebled.

Reference to Table II. will indicate the more important new stations besides those already described. In addition to the terminals listed, two new stations of large proportions were planned for Chicago. One of these, the new Union station, was already under construction in 1921, while the designs for the other, the Illinois Central or 12th St. station, had been approved by the railway and by the city authorities.

TABLE II.—Representative Railway Stations erected 1907-22.

Station	Date completed	Dimensions: main building ft.	Cost*
Washington, D.C.	1907	663 x 211	\$120,000,000
Pennsylvania, N.Y.	1910	430 x 430	115,000,000
Northwestern, Chicago	1911	320 x 218	24,000,000
Grand Central, N.Y.	1912	673 x 301	150,000,000
Ottawa, Quebec	1912	281 x 141	—
Michigan Central, Detroit	1913	345 x 266	7,000,000
Kansas City	1914	510 x 150	55,000,000
Havana, Cuba	1914	240 x 70	—
Buenos Aires	1915	850 x 606	—
Tokyo	1915	1,104 (Frontage)	1,350,000
Leipzig	1915	984 "	32,500,000
St. Paul, Minn.	1922	315 x 220	20,000,000

*Includes entire cost of terminal development.

Whether the expense of the more elaborate American terminals is justified in view of the limited profit obtained from passenger business is a question which gave rise to no little discussion. Estimates were made as to the number of miles of new track that could be laid with the money expended for terminals, and it was demonstrated in some instances that terminal charges were making serious inroads on passenger profits. "As showing what some railways are up against," said John A. Droege, general superintendent of the New York, New Haven & Hartford railway, writing in 1916, "it is worth noting that the New Haven has to pay 29 cents for each passenger it brings into the Grand Central terminal in New York." The U.S. Interstate Commerce Commission, in its report in the Anthracite case (35 I.C.C. 270), under the head of "Unproductive Betterments," said: "The Pennsylvania has expended on its new passenger terminal properties in New York City approximately \$114,000,000. These properties are operated by the Pennsylvania Tunnel & Terminal railway company, and the operations result in a deficit each year. The deficit in the year ended June 30 1913 was \$2,087,000. . . . Thus the question is presented: Must the present effective freight rates of the Pennsylvania earn an annual return of 6% on the investment in these terminal properties? The record shows that \$47,000,000 of the expenditures in this property has been charged to profit and loss and to income of the Pennsylvania—that is, its past surplus income has already contributed \$47,000,000 to the cost of this property." In answer to such criticisms Samuel Rea, president of the Pennsylvania lines, stated in 1917 that in seven years the traffic of the Pennsylvania station had increased from 9,862,434 to 18,135,311 annually, and that if the probable period of its usefulness was considered it could not be regarded as an unproductive betterment. He pointed out also that had the Pennsylvania waited longer to purchase a site in Manhattan the prices would have become prohibitive.

By leasing "air rights" and retail privileges within the station, the owners of the Grand Central terminal were able in 1920 to make an effective answer to criticisms of this sort. Following the example of the Grand Central, many railways sought to make their stations productive investments. Thus the Michigan Central constructed a seventeen-story office building in connexion with its station at Detroit, while the designers of the proposed Union station at Chicago, estimated to cost nearly \$100,000,000, altered their plans to provide for a huge office building over the head house and train shed. Closely connected with the criticism of expense was the criticism on the score of excessive size. Ironical references were made to the "magnificent distances" which passengers were compelled to walk between the street and trains. Examples of the distance walked by passengers purchasing tickets and checking baggage were given as follows: South station, Boston, 1,100 ft.; Northwestern, Chicago, 940 ft. and 20 ft. climb; Pennsylvania, New York, 480 to 950 ft., depending on the entrance used; Grand Central, New York, 450 ft.; Union, Washington, 1,200 feet. It should be said, however, that space is required if immense crowds are to be handled, and a slight extra walk is a small price to pay for freedom from the discomfort of crowded passage-ways. Nevertheless there were some leading railway men who believed that future development would be in the direction of more and smaller terminals located at various parts of a city. One proposal was to construct a system of subways, making each stop a Union Railway Station.

See J. A. Droege, *Passenger Terminals and Trains* (New York, 1916). (H. B. *)

RAINER, ARCHDUKE OF AUSTRIA (1827-1913), noted as one of the most cultivated and liberal-minded members of the Austrian imperial house, was born on Jan. 11 1827. His father, also named Rainer, the seventh son of the Emperor Leopold II. and of his consort Maria Luisa of Spain, was born in Florence in 1783, and from 1818-48 was viceroy of the kingdom of Lombardo-Venetia; his mother was the Princess Elizabeth, sister of Charles Albert, King of Sardinia. After serving in the army, the Archduke Rainer was in 1857 placed at the head of the permanent Imperial Council organized in 1851, which stood immediately under the Emperor and had among its functions the preparation of laws, and his experience in this office convinced him that the transition to a constitutional form of government on a liberal and centralized basis was necessary. In 1860 he conducted the negotiations for a strengthened Imperial Council; in 1861 he became head of the Government as president of the council of ministers of the Liberal Schmerling administration. His name is associated with the promulgation of the charter of the Constitution of Feb. 26 1861. In the same year Rainer became curator of the Academy of Sciences, a position which he filled till his death. In July 1865, when politics had shifted from the basis of the 1861 Constitution, he laid down office, and retired from public affairs. In 1872 he was appointed to the supreme

¹In 1921 36 cents (23 cents terminal entrance and 13 cents tollage), representing charges from Woodlawn (11 m.), not including cost of operation.

command of the newly established Austrian *Landwehr*, to the organization of which he devoted many years of work. He continued to take a keen interest in art and science. As patron of the Arts and Crafts Museum (1862-98), and as curator of the Academy of Sciences, he won a high reputation. He greatly furthered the general knowledge of antiquity by the purchase of the papyrus discovered at Fayum, which was called, after him, the "Rainer papyrus." He married in 1852 Marie Caroline, daughter of the Archduke Charles, the victor of Aspern. There were no children of the union. He died on Feb. 27 1913.

RALEIGH, OECIL (1856-1914), English actor and playwright, was born Jan. 27 1856. He was the son of Dr. John Forthergill Rowlands, and took the stage name of Raleigh. He played for a time in musical comedy, but deserted acting for playwriting and, either alone or in collaboration, produced an immense number of melodramas, staged at first chiefly at the Comedy theatre, London, and in later years at Drury Lane. *Cheer, Boys, Cheer* (1895); *Hearts are Trumps* (1890); *The Best of Friends* (1902) and *The Whip* (1909-10) are typical examples. He also acted as dramatic critic to two or three London papers, and became secretary to the School of Dramatic Art in Gower St., London. He died in London Nov. 10 1914.

RALEIGH, SIR WALTER (1861-), English man of letters, was born Sept. 6 1861 in London, and was educated at University College, London, and King's College, Cambridge. He was professor of modern literature at University College, Liverpool, and professor of English literature at Glasgow, and in 1904 was appointed professor of English literature at Oxford. He was knighted in 1917 and elected to a fellowship at Merton College in 1914. His publications include *The English Novel* (1894); *The English Voyagers* (1904); *Six Essays on Johnson* (1910); *Romance* (1917) and many essays on literary subjects.

RAMPOLLA, COUNT MARIANO DEL TINDARO (1843-1913). Italian cardinal (see 22.877). When Pius X. was elected Pope, Cardinal Rampolla resigned all his appointments, retiring into the background. He had always been filled with a high sense of the dignity of his office, and while secretary of state had entertained in princely style; but personally he was a man of austere habits, and after his retirement he led the simplest life. A sound scholar, he devoted his last years to study, particularly to hagiography and Christian archaeology. He died in Rome Dec. 17 1913.

RAMSAY, GEORGE GILBERT (1830-1921), British classical scholar, was born at Fontainebleau July 19 1839, the third son of Sir George Ramsay of Banff and a member of a well-known family of scholars. He was educated at Rugby and Trinity College, Oxford, where he graduated first-class in *Literae Humaniores* (1861). He then became assistant to his uncle William Ramsay, professor of Humanity at Glasgow, and succeeded him in 1863, occupying the chair until 1906 and becoming a great teaching force in defence of a classical education. He was the first president of the Classical Association of Scotland which he helped to found. He was also a keen politician and a considerable athlete. His published work includes a *Manual of Latin Composition* (3 vols., 1st ed. 1884, 4th ed. 1897); an annotated version of *The Annals of Tacitus* (2 vols. 1904-9) and of the *Historiae* (1915), as well as translations of Juvenal and Persius for the Loeb Library. He died at St. Andrew's March 8 1921.

RAMSAY, SIR WILLIAM (1852-1916), British chemist (see 22.880), died at High Wycombe July 23 1916. In 1904 he was awarded the Nobel prize, and in 1911 was president of the British Association. In 1913 he resigned his professorship of chemistry at University College, London. After his death a fund amounting to £53,772 was raised to perpetuate his memory by providing a laboratory of chemical engineering in connexion with University College, London, and founding Ramsay Memorial research fellowships of £300 a year each, tenable in any university in the United Kingdom for the advancement of chemical science.

RAMSAY, SIR WILLIAM MITCHELL (1851-), British archaeologist (see 22.880), resigned his professorship at Aberdeen

in 1911, and subsequently published *The Imperial Peace and The Teaching of Paul in Terms of the Present Day* (1913); *Recent Research and the New Testament* (1914); *The Making of a University* (1915) and the *Life and Letters of William Black* (1918).

RANDEGGER, ALBERTO (1832-1911), musical composer and conductor, was born in Trieste April 13 1832. He settled in London in 1854 after holding various musical appointments in Italy. Both as an orchestral conductor, and as a teacher of music and singing he held for many years a leading position in London. Besides conducting on various occasions at the Royal Opera, musical festivals and elsewhere, he did much, as conductor of the Carl Rosa company from 1879, towards the popular revival of opera in England. He died in London Dec. 18 1911.

RANGE-FINDERS AND POSITION-FINDERS (see 22.888).—Recent improvements have rendered many of the earlier types of range-finders obsolete, and the following features are common to all modern coincidence range-finders. The range-finder usually consists of two main parts, viz:—a strong outer tube and an inner frame which supports the delicate telescopic system, any slight derangement of which would seriously upset the accuracy of the range-finder. The outer tube is made as strong and rigid as possible, having regard to the weight which can be allowed. The inner frame is supported in such a way that any slight bending of the outer tube will not affect it.

Some form of double end reflector is always used. This at one time consisted of a pentagonal prism, but large pentagonals are very costly; they absorb a good deal of light and are liable to slight distortion with changes of temperature. There is therefore a tendency to replace them by a combination of two silvered plane mirrors inclined to one another at 45° , and either fixed in a mount made of a metal having the same coefficient of expansion as glass, or rigidly attached to an upper and lower glass support, to prevent change in their relative positions.

The central reflectors usually take the form of two or more prisms balsamed together, and are known as the centre prism combination. Their object is to deflect the rays received through the two ends of the range-finder into the eye-piece, and to present the two images of the target in the field of view immediately above and below a thin separating line. Their construction is usually rather complicated. The fine separating line is as a rule obtained by means of a special separating prism; or by the edge of a silvered surface on one of the prisms, so arranged that the rays forming one image pass through the prism, and those forming the other image are reflected by the silvered surface.

The centre prism combination is also used for erecting or inverting the images, and for defining the limits of the fields of view received from each half of the range-finder. The arrangements of fields of view usually met with are the following:—

1. The field of view is divided into two equal halves and the images in both are erect. When a coincidence has been made, the separating line cuts straight through the image of the target. This system is used with naval and coast defence range-finders which have to deal with targets having long vertical features, e.g. masts and funnels. It is known as the "erect" system.

2. The field of view is divided into two parts by the separating line. One field (in field range-finders usually the lower) is erect, and the other one is a replica of it, being inverted up for down but not right for left. With this system it is much easier to make an accurate coincidence on small targets, but it has the slight drawback that the total actual field of view is necessarily considerably smaller than with the erect system, and a slight elevation or depression of the range-finder may cause the target to pass the separating line and disappear. This, however, is not of much importance if the target is a stationary or slowly moving one. The upper field is often made smaller than the lower, so that as much ground as possible may be seen in the field of view. This system is known as the "invert," and is used in many field range-finders.

3. The whole field is erect with the exception of a small central rectangle in which the image is inverted. The advantage of this system is that the field of view is as large as that of a range-finder of the erect type, except that the part covered by the rectangle is missing. It is known as the "invert rectangle" and is used in many field range-finders, especially in foreign armies.

4. The whole field is erect with the exception of a narrow horizontal strip which passes right across its centre. The field in the strip may be either erect or inverted. This system, known as the "strip" system, is used in the British height- and range-finder.

In early range-finders the axis of the eye-piece was horizontal when targets in the horizontal plane were being viewed. It is now usually inclined downwards at angles of 45° , 60° , or even 90° for anti-aircraft work, so that the range-taker can observe from a more comfortable position. Eye-pieces can be focussed for individual observers, the two images of the target and the separating line coming to focus simultaneously. Coloured and neutral tinted glasses are useful in cutting out excessive glare, haze, etc. In some range-finders, the magnification of the eye-piece can be altered so as to obtain the best effect under various atmospheric conditions. Astigmatismers are sometimes used for drawing out a point of light or small object into long lines or bands. Coincidence, which without their use would be almost impossible to effect, can then easily be made. They consist of two negative cylindrical lenses with horizontal axes, one being placed at each end of the range-finder between the pentagonal and the objective.

Range-finders are provided with halving and coincidence adjustment heads, which, when turned slowly, move the optical systems mentioned above. Correct adjustment is of course essential for accurate work.

Accuracy of One-man Range-finders.—The accuracy of the range-finder, other things being the same, depends upon its base length and magnification; but there are limits to the magnification which can be conveniently used. It is usually between 10 diameters (for the smaller range-finders) and 30 (for the largest). Under good conditions, two images can be aligned across a fine separating line, with an error of only a few seconds. There is little doubt that this degree of accuracy can be obtained under the best atmospheric conditions and when the target is stationary, as the mean result of several observations being taken as the range. If, however, the atmospheric conditions are bad and the target is moving rapidly, such accuracy cannot be expected.

The base lengths of range-finders used in the field usually vary between half a metre and two metres. The Barr and Stroud range-finder with a base of one metre, which is used for field artillery by the British and other armies, is typical.

German field coincidence range-finders, such as the Zeiss and Goerz, are used in a similar way to the Barr and Stroud, although their construction differs materially in details. Many of these were introduced to avoid infringements of earlier patents. The chief features of Zeiss coincidence range-finders are that they have only one eye-piece in which are seen a small rectangular inverted field in the centre of a large erect field and on the left of these a range scale. Coincidence is effected by revolving a working head which rotates two wedge-shaped prisms in opposite directions.

Stereoscopic Range-finders.—The principle of the stereoscopic range-finder is entirely different. Stereoscopic range-finders have not found much favour in the British services; but they have been extensively used by the Germans. Speaking generally, a stereoscopic range-finder contains the elements of a stereoscopic telescope rigidly mounted in a tube. It is very similar in outward appearance to a coincidence range-finder with two eye-pieces. Objects viewed through a stereoscopic range-finder are seen to stand out in stereoscopic relief; and it is comparatively easy for the observer to judge their relative distances. The actual distance of a target is obtained with the assistance of one or more marks which are seen in stereoscopic relief in the field of view. By means of suitable optical arrangements the stereoscopic relief of either the objects in the field of view or of the mark can be varied until the target and mark appear to the observer to be the same distance away from him. The range of the target can then be read off a range-scale attached. The mark which is seen in stereoscopic relief, really consists of two similar marks which are photographed on glass diaphragms mounted in front of the eye-pieces of the range-finder. If the two marks are on the optical axes of the two halves of the range-finder, they will appear to the observer as one mark at an infinite distance. If the two marks on the diaphragms are made to approach one another, the resulting single mark will appear to come towards

the observer. In the later stereoscopic range-finders, marks in the eye-pieces are adjusted so as to appear to be at a fixed distance when seen stereoscopically. The view containing the target appears to approach or recede from the observer when the working head is turned; and the range is read off from an external range scale or drum.

Stereoscopic range-finders suffer from the disadvantages that very few people are able to see stereoscopically with sufficient exactness to obtain good results and the degree of accuracy obtained by a range-taker appears to vary from time to time. Under the same atmospheric conditions, stereoscopic range-finders do not appear to give such good results as coincidence ones. Owing to the marks on the diaphragms in the eye-pieces being more distinct than the image of the target, there is difficulty in deciding when they are at the same apparent distance. On the other hand, owing to both eyes being used, the target should be seen more distinctly than through a coincidence range-finder. Ranges of targets with the sky as a background, e.g. aircraft, masts of ships, and trees on a crest line, are comparatively easy to take with a stereoscopic range-finder; but those of comparatively indistinct objects, objects with near backgrounds and objects in a shadow, e.g. a gun under a tree, are very much more difficult to take.

Directors.—The director is an instrument employed chiefly for the measurement of azimuth angles and angles of sight. There are numerous patterns of these instruments. Some are of simple form; while others are complicated and are provided with quick and slow motion movements for their azimuth and altitude movements and for laying on a gun or target without the setting of their azimuth scales being altered. Some are used as directors pure and simple, whilst others are provided with powerful telescopes for observing fire. British directors are graduated in degrees and minutes, whereas those of nearly all other powers are graduated in millimetres. Instruments graduated in millimetres can be made much more compact than those graduated in degrees and minutes, as the main azimuth plate has only 64 divisions instead of 360. The azimuth scales of some German directors are graduated in 16ths of a degree and 16ths of a degree are also sometimes used for angle-of-sight scales.

The German director for field artillery is a good example of modern types of this instrument. Powerful telescopes like the stereoscopic or scissors telescope are often provided with fittings which enable them to be used as directors as well as for observing fire. Azimuth angles can be measured by means of an azimuth scale, and angles of sight by means of a small bubble and scale. In one pattern of German stereoscopic telescope, the angle of sight is measured by means of a device which is compactly placed between the two arms of the telescope, above its elevating gear.

The Field Plotter is an instrument used for obtaining the gun range when the range-finder is not near the gun. It consists of two similar nickel-plated steel plates, having azimuth scales and a scale of yards (upon which the distance of the gun from the range-finder can be set) engraved upon them, and two range arms which are pivoted at the centres of the azimuth scales and connected by means of a slider. The two plates are slid along one another until the distance between the gun and the range-finder is opposite the reader. The slider is then moved until an arrow upon it reads on the arm the distance from the range-finder to the target. The arm is then moved until another arrow reads the angle, recorded by the director, between the target and the gun. The plotter is then turned over, and the range from the gun to the target and the angle at the gun between the target and the director are read off. When fire has been opened, it is necessary to observe the results, so that corrections for both range and direction may be made. Also if time fuzes are used, the angular height above the target at which they burst the shell must be observed and corrected if necessary. Various instruments, e.g. graticuled binoculars, stereoscopic telescopes and periscopes, are used for this purpose.

The binoculars used in the British service are of the prismatic type having a magnification of six diameters and are fitted with

a glass diaphragm in front of the right eye-piece on which are engraved the vertical lines $\frac{1}{2}^{\circ}$ apart; their heights above the horizontal line being alternately $\frac{1}{2}^{\circ}$ and 1° . The central line is longer, extending $1\frac{1}{2}^{\circ}$ above, and $\frac{1}{2}^{\circ}$ below the horizontal line. When observing fire, the point of intersection of the centre vertical line with the horizontal line is laid on the target; and, when the burst of the shell is observed, its angular distance to the right or left of the target and above it can be ascertained by noting its position with reference to the lines on the diaphragm. Graticules used by other continental powers vary very much in design and often consist of a very large number of short lines at definite distances from the axis of the telescope.

The stereoscopic or scissors telescope was very largely used in the World War, especially by the Germans. The British pattern has a magnification of 10 diameters and a field of view of 4° . The two arms can be used either vertically for observation from below cover, or in line with one another for observation from behind vertical cover.

FOR COAST DEFENCE

Coast defence range-finding instruments are usually either range-finders or position-finders. A range-finder measures ranges from itself to the target and may also record the bearing of the target. A position-finder measures ranges and bearings to the target from the point for which it has been adjusted. This would usually be a gun which may be many hundred yards away from the position-finder. The position-finder sometimes also records the range and bearing of the target from its own position. Coast defence range-finding instruments may be divided into classes, depending upon the nature of their bases, as follows:—

1. **Depression instruments**, having vertical bases (either range-finders or position-finders) the accuracy of which depends upon their height above the sea-level. They measure ranges with equal accuracy in all directions; and, if sufficient height is available, they are most reliable instruments. It is usually considered that, to obtain ranges with an error not exceeding 1%, 100 ft. of height is required for every 5,000 yd. of range. All that the range-taker has to do is to keep a cross wire in the telescope of his instrument laid on the water line of the target.

2. **Instruments having a fixed horizontal base** (usually position-finders). Each usually consists of two instruments installed at the ends of a base which may be several thousand yards in length, the length required depending upon the range and arc of fire of the gun for which the instrument has been installed. The instrument at one end of the base is known as a transmitter and usually consists of a telescope mounted above an azimuth circle. It measures the bearing of the target and transmits it to the instrument at the other end of the base which is known as the receiving instrument. The bearings may be transmitted by telephone; or, as the telescope is traversed, electric impulses may cause some portion of the receiving instrument, e.g. a metal arm or a dial, to move automatically. The receiving instrument is usually an accurate, solidly constructed plotter, made to a certain scale, e.g. 500 yd. to an inch. In its simplest form it would consist of a base plate upon which two straight arms were pivoted, the relative positions of the pivots being, to the scale of the instrument, the same as those of the transmitter and receiving instrument. The first arm would be kept set to the azimuth angles received from the transmitter, and the second arm would be kept in line with the target by means of a telescope attached to it. The point where the two arms intersect would represent the relative position of the target. The arms being graduated in ranges and moving over azimuth scales, the range and bearing of the target from either end of the base could be read off. By means of a third arm, pivoted to the base plate in the position representing the position of the gun, the range and bearing of the target from the gun could be ascertained if the arm were brought above or below the point of intersection of the two other arms. Horizontal-base range-finding instruments are often designed to allow of several alternative bases being used, the pivots of the arms in the receiving instrument being set for the base which is most suitable for the conditions prevailing at the time. Thus for very long ranges a very long base would be used; but, if the visibility were bad, a much shorter one might be preferable. Horizontal-base instruments have certain disadvantages. For a definite range, their accuracy varies with the position of the target. It is greatest when the target is opposite the centre of the base, decreases as the target moves to the right or left, and disappears altogether when the target is in line with the base. It is somewhat difficult for the receiving instrument to indicate to the transmitter the target whose range is to be found. There are difficulties in passing azimuth angles from the transmitter to the receiving instrument. If they are telephoned, delay and errors are involved, and owing to the fact that they may

alter at greatly varying rates there is usually some uncertainty as to the most suitable intervals in which they should be called out. If they are electrically transmitted, so as to move some part of the receiving instrument, the mechanism must be capable of moving in small steps of, say, one minute, in order to obtain the required accuracy, and at the same time it must be capable of moving quickly through a large angle when getting on to a target.

3. *One-man Range-finders* used for coast defences are constructed on the same general principles as those used in the field; but, as their weight and size must not be limited to the same degree, many modifications to make them as accurate and convenient as possible are introduced. Their base lengths are usually between 9 ft. and 10 metres, but even longer bases have been considered. They are practically always of the coincidence type with both fields erect.

The *Mark III Depression Range-finder* (fig. 2) will be taken as a type of a depression instrument. In this range-finder the range-finding triangle is reproduced in the instrument on a small scale. Figure 1 shows diagrammatically how this is effected by means of

FIG. 1.

two arms. AB represents the height of the axis of the telescope above the surface of the sea BC. Ab represents the distance between the pivot of the telescope arm Ac and the range arm bc, and this to the scale of the instrument, represents the height AB. When the instrument is level, the arm cb is horizontal, and therefore parallel to the

FIG. 2.—Depression Range-finder Mark III.

surface of the sea. cb is subdivided and graduated in equal divisions to the scale of the instrument. Ac, which has a telescope mounted on it, is pivoted at A and can be directed on to the water-line of a target at C. The triangles ABC and abc are similar, and the length of bc therefore represents to the scale of the instrument, which is 1,000 yd. to an in., the actual range BC. Similarly bd will represent the range BD of a target at D. If the instrument is required for use at any other height than AB, the telescope arm pivot A would be raised to a height above cb corresponding to the new height of the range-finder above the sea. In the foregoing, the surface of the sea has been considered as a plane surface, whereas it is really the surface of a sphere with its centre at the centre of the earth. Allowance for this curvature could be made by making the arm be the arc of a circle instead of a straight line. It is, however, found to be more convenient to curve the telescope arm Ac in the opposite direction, the effect being the same. Corrections for mean refraction are made in the same way as those for the curvature of the earth, but in the opposite direction; the arm Ac being curved to allow for the combined effect of curvature and refraction.

The *Small German Position-finder* may be taken as a typical position-finder. It was used during the World War for coast artillery on low sites. Very much larger instruments based on the same general principles were also used. Air communication was by telephone. Other nations often use automatic electrical transmission for moving parts of the receiving instrument when the transmitter telescope is traversed, and for actuating range and bearing dials on the gun mountings when the gun arm is traversed.

The *Barr and Stroud Range-finder* having a base-length of 30 ft. is typical of the one-man range-finder used for coast defences.

None of the range-finders or position-finders mentioned above is of any use if it cannot see the target; the position of a moving target can then only be ascertained by aerial observation.

Naval Range-finders, which must necessarily be of comparatively small size, are nearly always of the one-man type. They are generally similar to those used in coast defences, but, in order to obtain better illumination their optical parts are often made larger. Their mountings are designed to enable the range-finders being kept on the target in a sea way. They are nearly always of the coincidence type with both images erect; but some stereoscopic range-finders have been used by the Germans. It is thought by some that a range can be more rapidly taken from a ship having considerable motion with a stereoscopic range-finder than with a coincidence range-finder; as with the latter it is difficult to keep the separating line across the target. The coincidence range-finder will, however, give more accurate results. Range-finders with a base-length of 10 metres are the largest which can conveniently be used on board ship. Base lengths vary with the size of the ships on which the range-finders are employed and the uses for which they are intended; one of less than a metre being employed for navigational purposes. Anti-aircraft range and height-finders used on ships must be provided with some form of pendulum to keep certain of the parts horizontal, as the mountings cannot be kept level. Certain small range-finders have been made which can measure the range to a ship if the height of its mast or funnel is known. This height is used as the base of the range-finding triangle, the angle of parallax being measured by the instrument and read off it as a range. Such a base is obviously longer than that of a range-finder which could be carried on a ship. This type, however, has not been generally adopted.

FOR AIR DEFENCE

Range-finders and height-finders used in connexion with anti-aircraft guns have a much more difficult task to perform than the range-finding instruments used in the field or in coast defences. In the latter cases the target, if it moves at all, will move in one plane only and its speed will not approach that of aircraft. As the result of experience, the range of an aerial target which may alter by several thousands of yards in a minute is not taken into account; but its height, which will not vary to the same extent, is used as the basis of laying & is measured by a height-finder. The rate of burning of the fuse has also to be considered, as it will not be the same for a definite range if the target is at different heights.

When laying a gun on aircraft, the setting of the sight is therefore based on the height and angle of sight of the target and on the setting of the fuse. At the beginning of the World War, no height-finders were available, so existing one-man range-finders, e.g. the Barr and Stroud, were used, and long base height-finders which could be rapidly made were introduced.

FIG. 3.

One-man range-finders were usually of two metres base length, and coincidences were made on the target in the usual way. In order to convert the ranges into heights, a slide-rule attached to the range-finder was employed. One scale of this slide-rule was automatically set to the angle of sight of the target, by means of a cam, as the elevation of the range-finder was altered. The other scale was set to the range recorded by the range-finder, and the height of the target could then be read off.

Long base height-finders usually consist of two instruments at the ends of a base about a mile in length. Sighting planes in these instruments are kept laid on the target; the triangle formed by the intersection of a vertical plane with three planes, one of which is a horizontal plane passing through the base and the other two are extensions of the sighting planes, is mechanically solved; and the height of the point where the two planes of sight intersect (i.e. the height of the target above the base) is plotted at the same time.

The principle of this method is shown in fig. 3. AX and BY are two horizontal lines, parallel to each other. The sighting planes of

the instrument would be attached to axes whose axes were on any parts of AX and BY. AXQZ and BYQZ represent planes of which the sighting planes form small parts. It is obvious that QZ is horizontal, and that ZK, PL or any vertical line between QZ and the horizontal line KL (which is parallel to the axes of the sighting planes) represents the height of an aircraft in the line ZQ, say at P. In the simplest form of height-finder, the plotting is done on a board fixed beneath B, the triangle AZB being reproduced there on a small scale and upside down. A straight edge is attached to the sighting frame at B and consequently moved round B in front of the board as the elevation of the frame is altered. Another straight edge is pivoted on the right of B at a distance from it which represents AB to the scale of the instrument. It is kept set to the altitude angle which is measured at A and telephoned to B. The point where the two straight edges intersect consequently represents the point Z. Upon the board below B, a series of horizontal lines are marked, their distance from a zero line passing through the pivots of the straight edges representing heights above the ground, to the scale of the instrument. The height of the target can therefore be ascertained by noting against which of the horizontal lines on the board the intersection of the two straight edges comes. Such height-finders have serious disadvantages, the principal one being the difficulty in getting the two instruments on to the same target.

Height- and Range-finder.—Towards the end of the war Messrs. Barr and Stroud produced a most ingenious instrument which recorded both the height and range of aircraft, and which was at once adopted by the British Government.

It is used in a similar manner to an ordinary one-man range-finder, and the observer has only to keep the aircraft in the field of view and make coincidences. As will be explained later, if the height of the aircraft remains constant the coincidence will not alter as the range alters. The field of view is so arranged that the rays of light entering by the left window of the instrument form an erect image over the whole field, with the exception of a narrow central horizontal strip in which an inverted image is formed by the rays entering by the right window. The lower separating line is the one on which coincidences are made. The advantage of this "strip" system is that it is considerably easier to keep the aircraft in the field of view than if the field were divided into two equal parts, one of them being inverted. As in field instruments, the inversion of the image in the field above the separating line is found to facilitate making accurate coincidences.

The eye-piece of the range-finder is placed at right angles to the plane of triangulation, so that if the angle of sight to the target is 60° the observer looks down at an angle of 30° . It is provided with two lens combinations on a rotatable cap which give magnifications of 15 and 25 diameters, and also with light filters for varying atmospheric conditions. There is a window above and to the left of the eye-piece, through which the usual ivory range scale can be seen.

In a small casing on the top of the range-finder there is a most ingenious mechanism which converts ranges into the heights corresponding to them as the angle of sight varies. The ranges and heights can be read through two windows in close proximity to one another. This mechanism actually solves the trigonometrical formula $r \sin a = h$; where r is the range of the target, a the angle of sight to it, and h its height. This formula may be written as: $\log r + \log \sin a = \log h$; and it is mechanically solved as follows:—A differential gear is employed, the upper member of which is rotated in accordance with a logarithmic sine scale of angles of sight, and the lower member is rotated in accordance with a logarithmic scale of ranges, the jockey wheel accordingly revolving around the axis of the differential with a motion corresponding to a logarithmic scale of heights. It will be noted that the angle of elevation and the range are known, or rather are determined by the instrument, so that the duty of the gears is to convert the angle and range scales to logarithmic form and then to add them together by means of the differential gear as explained above. The conversion of the reciprocal range scale motion of the range-finder deflecting prism gear into logarithmic range scale motion, and the angular motion of the range-finder in elevation into motion corresponding to a logarithmic scale of sines, is done in each case by means of toothed spiral gears.

The gearing is connected through three couplings to the working head, the elevation gear and the deflecting prism gear respectively. By means of suitable gearing the jockey wheel of the differential is driven from the working head, the upper member by the elevation gear, and the lower member by the deflecting prism gear. The range scale is connected to the lower member, and the height scale to a level wheel carrying the jockey wheel.

The advantage of arranging the working head to operate the jockey wheel is that in the frequent case of aircraft flying at a constant height the images in the field of view, when once set, can be kept in coincidence by simply elevating the instrument so as to keep the target in the centre of the field, without any rotation of the working head. The movement of the instrument in elevation automatically controls the position of the deflecting prism, the height scale remaining unaltered so long as the working head is not rotated. When the target rises or falls, the images will move out of coincidence and must be brought back into alignment by rotating the working head, thus altering the reading of the height scale by the appropriate amount. The working head and elevating gear may, of

course, be worked at one time, in which case the combined effect of the spiral gears and the differential is that the two scales always read correctly as long as the coincidence is maintained.

The instrument has a base length of two metres, and is carried in the mounting forks in two eccentric bearing rings, the object of the eccentricity being to balance the weight of the height-scale gear box as the instrument is rotated in elevation. The elevating gear, with a handwheel on the left of the observer, is of the worm-wheel type. The handwheel is provided with a two-speed clutch; the speed being changed by merely pressing in or releasing, with the palm of the hand, a small lever connected with the hand grip.

The azimuth training gear is also of the worm and worm-wheel type and has a two-speed clutch. Its handwheel is on the right of the eye-piece, and in a convenient position for the man who, looking through a small prismatic telescope near the right-hand end of the instrument, keeps it laid for direction on the target.

The worm wheels for movements in both azimuth and altitude are mounted on friction slip-bearings, so that the instrument can be rapidly moved and the target brought into its field of view. An elevating lever is fitted near the left-hand end of the instrument to allow of rapid elevation. An adjustable azimuth scale and reader are provided; and a means of levelling the upper part of the mounting. Before using the instrument, its correct levelling must be attended to and checked by means of two bubbles attached to the upper part of the mounting. The lower part of the mounting is a very rigidly constructed tripod with pointed feet having discs to prevent their sinking into soft ground.

Three operators are required for working the instrument, viz.: (1) The observer who makes "coincidences" by turning the working head on the top of the instrument with his right hand, and who also keeps the separating line on the target by turning the elevation handwheel with his left hand. (2) The operator for line who, looking through the prismatic sighting telescope, traverses the instrument with the handwheel and keeps the cross line in his telescope accurately laid for line on the target; and (3) the scale reader, who, standing in front of the instrument, reads heights off the height scale; and, if required, also reads the range and angle of sight scales.

In anti-aircraft gunnery, where the target may move at a speed of two or more miles a minute, there is great difficulty in ascertaining what deflections are required to compensate for the travel of the target during the time of flight of the projectile. There is not only the lateral deflection to be considered, as with a ship moving in one plane; but also a vertical one. It is obvious that if an aircraft is flying at a constant height, the angle of sight to it from the gun will not remain constant. Vertical deflection equal to the alteration of the angle of sight during the time of flight of the projectile must therefore be allowed for. Another difficulty arises in connexion with the setting of the fuze. The fuze will not burn at the same rate if the projectile is fired at different angles of sight, owing to the variation of atmospheric pressures at different heights. To help to overcome these difficulties a most ingenious apparatus was brought out during the war by Messrs. Brocq of Paris, and was adopted by most of the Allied Powers.

The general principle of the instrument is as follows:—The height of the target must first be measured by a height-finder and set on the instrument. Two operators, who face one another, follow the target, looking through two telescopes which are rigidly connected. One keeps a vertical cross line in his telescope in line with the target by turning a traversing handle; and the other keeps a horizontal cross line in line, by turning an elevating handle. Connected with the traversing and elevating handles are the armatures of two magnetos which, when turned, generate electric currents, the voltages of the currents depending upon the speed at which they are turned. These currents are transmitted to two special voltmeters (attached to the gun mountings near the layers) from which the lateral and vertical deflections required can be read off, and then applied to the sights. On their way to the voltmeters the currents pass through rheostats which modify them in such a way that the deflections recorded are correct for the time of burning of the fuze. The exact length of fuze required to burst the shell at the target can also be read off another part of the instrument.

The general arrangement of the apparatus is shown diagrammatically in fig. 4. It consists of three main parts, viz.:

1. The double telescope, which consists of a metal drum upon which are mounted, on the same spindle, the two right-angle telescopes referred to above. The traversing and elevation handles are placed conveniently for the two operators. Each has a quick and slow motion (four to one), the alteration from one to the other being effected by pushing in or putting out the handle. When a quick release knot at the top of the instrument is pressed down, the gears are put out of action, and the telescopes can be quickly moved until the target is in their fields of view. Angles of sight and bearings can be read off conveniently placed scales, if required. When the handles are turned, the currents generated by the magnetos pass off

cables to the "fuse indicator and time rheostat" and thence to the "deflection voltmeter."

As the body of the "double telescope" traverses about a vertical axis, but laying is done in the plane of sight, it is necessary to multiply the angular velocity of the body of the instrument by the cosine of the angle of sight in order to obtain the angular velocity of the target. This is effected electrically by passing the current from the lateral magneto through a rheostat, whose resistance is varied by a rubbing contact passing along it, as the telescopes are elevated or depressed.

Another rheostat and an accumulator (connected to the fuse indicator and time rheostat) cause an angle of sight needle in the fuse indicating voltmeter to move to the same angle of sight as that of the telescopes; this needle is controlled by another circuit.

2. The fuse indicator and time rheostat consist mainly of the time rheostat, a fuse indicating voltmeter, a microphone and an external accumulator of three cells.

As explained above, the currents generated by the magnetos pass through rheostats on their way to the deflection voltmeters. These rheostats are situated beneath the time adjusting dial, and their resistance is altered as the dial is turned. The setting of the dial is dependent upon the height of the aircraft and the setting of the fuse, and is effected as follows:—A graduated height arm is moved by means of a milled head until it reads the height obtained from a height-finder. On its right-hand upper edge is a reader for reading the fuse curves on the time adjusting dial. The latter is turned until the reader of the height arm is on the fuse curve representing the length at which the fuzes have been set.

FIG. 4.—Arrangement of Brocq apparatus.

The angle of sight needle in the fuse indicating voltmeter is controlled by two circuits, viz.: that referred to in (1) which tends to set it at the angle of sight of the telescopes, and another in which are the vertical magneto armature in the double telescope, the rheostat beneath the time adjusting dial and another rheostat which automatically adds eight seconds to the time of flight. This eight seconds is an allowance for the time taken to set the fuse, load, lay and fire the gun. The angle of sight needle therefore makes with its zero or horizontal line an angle equal to the angle of sight to the predicted position of the target at which the shell will burst. When the height arm is moved, a height strip inside the fuse indicating voltmeter is also moved. Its height above the zero line of the angle-of-sight needle represents, to the scale of the instrument, the height of the target. The intersection of the needle and strip therefore represents the position of the target at the moment of the shell burst. Fuse curves are marked on the glass cover of the voltmeter, and the curve which is nearest to the intersection of the needle and strip will indicate the length at which fuzes are to be set. This fuse length is called down the microphone to the fuse setters, and is transmitted to the sight setter by the man taking up the shell.

3. The deflection voltmeters are of the dead-brat type and read to 10° on either side of zero. Two are provided for each gun; one for lateral and the other for vertical deflection. As a rule, two guns can be worked by one Brocq equipment, four deflection voltmeters being provided. The required deflection is read by the upper pointer. Corrections for wind are applied by moving the scale by means of a knob beneath the voltmeter, the amount of correction being indicated on the scale by the lower pointer.

Stereoscopic range-finders were extensively used by the Central Powers for anti-aircraft work. (A. C. W.)

SOUND-RANGING

The method of locating hostile guns by the sound, or sounds, consequent on their discharge was introduced on the British front in France during 1916. It had at that time already been in use in the French army for many months. It speedily proved its usefulness, especially in circumstances which rendered other methods of location very difficult or impossible. The system

of concealment known as "camouflage" added considerably to the difficulty of finding the position of gun-pits on photographs taken from the air, and, further, these photographs offered no certain method of deciding whether a gun position, once identified, were occupied or no. The locations given by sound-ranging frequently enabled well-concealed positions, which had previously been missed on air photographs, to be detected, and offered a sure index as to whether known positions were active at a given time. Although air photographs always offered valuable confirmation of the sound-ranging locations, and were, when available, consulted with this object in view, the method is, of course, quite independent of such support. It works as well at night, or when, owing to fog, mist, or smoke, the visibility is poor, as on clear days; it can detect batteries so well hidden as to be invisible from the air or on air photographs; it is always ready when once the apparatus has been installed; and a location can be obtained, under favourable conditions, within a minute or two of the arrival of the report of the piece. On the other hand the instalment of the apparatus necessitates the laying of several miles of wire, and involves considerable preliminary labour in other ways; the method will not work during a heavy bombardment; and certain weather conditions, to be discussed later, render locations almost impossible. The difficulty first mentioned will quite possibly be surmounted or diminished; the other two seem, at present, insuperable.

The method has been elaborated to permit the directing of fire on a hostile piece by comparing the record of the sound of discharge of the piece with that of the burst of the shell directed against it. With 12-in. and 9.2-in. howitzers destructive shots have been directed very successfully by sound-ranging.

Principles.—The method generally adopted in the British, French, and American armies is to record the instant of the arrival of the sound made by the hostile piece at certain fixed and carefully surveyed posts, spaced at intervals varying from 1,000 to 2,000 yards. If it be assumed that the sound spreads out from the source with a known velocity, the same in all directions, then a known interval between the arrival of the sound at two fixed posts will determine a curve on which the source must lie. This curve is a hyperbola with the two posts P_1 and P_2 as foci, for the determining condition is that the difference of the radii vectores SP_1 , SP_2 be constant. If, in addition, the time of arrival at a third post be known, then the interval between this and the time of arrival at either P_1 or P_2 will fix a second hyperbola on which the source must lie, and so determine the position of the source. In practice three posts are not sufficient, since any uncertainty caused by the recording of a spurious sound at a post would falsify the location. In general six posts are used, which, taken consecutively in pairs, give five lines which should all intersect. Any accidental selection of the record of a spurious sound at one or more of the posts is then at once detected by the non-intersection of the curves. Records of the sound at five, or indeed four, of the posts are generally sufficient for the experienced sound-ranger, even when several guns are being recorded at short intervals, so that the use of six posts allows for the sound not being successfully recorded at one or two of the posts.

Nature of Sounds from High-Velocity Guns.—In the preceding argument it has been assumed that the sound spreads out with uniform velocity in all directions from the source. There is little doubt that this is true, in a still atmosphere of uniform temperature, of the sound of the discharge of the piece. With the modern high-velocity gun, however, a second sound, originating in the motion of the shell through the air, always accompanies the sound of discharge. This second sound is due to a pulse of compression set up by the shell, known as the "shell-wave," or "ondé de choc." It is perceived by an observer in front of the gun as a sharp crack, which is followed after an interval depending on the type of gun, the elevation of the gun, and other factors, by the duller, heavier sound of the discharge, or gun-wave. To examine the formation of the shell-wave by the passage of the projectile, consider the resultant disturbance produced by the pulses of compression travelling out with the velocity of sound from every point of the path of the shell. For simplicity take in the first case a projectile travelling horizontally with a uniform velocity greater than that of sound; let G be the position of the gun, S_1 , S_2 , . . . S_{10} be the positions of the projectile at the end of the 1st, 2nd, . . . 10th second (fig. 5). When the shell is at S_{10} the compression originating at G has travelled out as a spherical shell with G as centre for 10 seconds, that originating at S_1 has travelled out as a spherical shell with S_1 as centre for 9 seconds, and so on. The envelope of all these spheres is a cone with its apex at S_{10} ; if the shell be travelling close to the surface of the earth the trace of this cone on the surface is $AS_{10}C$, which represents the pulse of compression under discussion. If the velocity of the shell be considered to decrease with time, as in any actual case, the

interval of space between centres of successive generating spheres will decrease as the shell travels, and the enveloping cone will be modified (fig. 6). The form of the shell-wave will resemble roughly a paraboloid of revolution, the vertex being at the shell as long as the latter has a velocity exceeding that of sound, and consequently travelling with a velocity greater than that of sound. After the velocity of the shell has dropped below that of sound the shell-wave travels out in all directions with the velocity of sound normal to the surface.

FIG. 5.

The exact form of the shell-wave will depend upon the range table of the gun and the interval since the shell left the gun, and cannot be specified as being any familiar surface. The trace of the wave on the plane of the earth's surface, with which the observer is in general concerned, depends further upon the elevation at which the gun is firing. Since the sphere representing the position of the gun-wave is one of the generating spheres the shell-wave will touch this sphere. In fig. 6 where G is the gun, ABC the trace of the gun-wave on the horizontal plane, ASC the trace of the shell-wave, within the cone represented by AGC both sounds will be heard, outside the cone only the sound of discharge. The interval between the two sounds is

FIG. 6

clearly greatest on the line of fire, decreasing as the observer moves to a flank. As the gun is elevated the interval detected by a listener in a fixed position decreases, the trace of the shell-wave approaching that of the gun-wave. This is illustrated in fig. 7. If the gun be sufficiently elevated no shell-wave is heard by a listener at any position on the ground, though it may be heard in an observation balloon. Thus the double sound has been heard by an observer so situated in the case of a 9.2-in. howitzer, firing with full charge (M.V. 1,500 f.s.), while observers on the ground heard only the single sound.

Owing firstly to the selective sensitiveness of the human ear; and secondly to the fact that the shell-wave is generated well above the surface of the earth, and travels down to the ear without meeting obstacles and without being hindered by refraction effects, the shell-wave alone is usually heard when the hostile piece is distant, and is spoken of as the sound of the piece by the casual listener. Any attempt to take rough bearings on a gun by estimating the direction from which the sound appears to be coming then leads to a very erroneous result, since it is the normal to the shell-wave that is selected. Unless the listener is on the line of fire such a bearing will pass considerably in front of the piece. To calculate the position of a gun from the intervals between the arrival of the shell-wave at different posts requires a knowledge of the exact form of the wave in question at various times of flight, and this presupposes a knowledge of the range table of the gun, and the elevation at which it is firing (given by the approximate range). It is clear that to apply the sound-ranging method to records made by the shell-wave is a matter involving information not always available, and considerable preliminary work on the construction of curves representing shell-waves for different hostile guns firing at various elevations when it is available.

FIG. 7.

In the case of howitzers the horizontal component of the muzzle velocity is less than the velocity of sound in all ordinary cases, so that only one sound, the gun-wave, is heard on the ground.

Instruments.—The instruments comprise: (a) detectors, placed at each of the six surveyed posts, which give an electrical response to the arrival of the sound, and (b) a recording instrument, placed at a central station and connected by a separate circuit to each detector, which registers the exact time at which each detector responds.

When the method was first tried by the French the detector used was a soldier, who pressed a key when he heard the sound of a hostile piece, the key closing a circuit which actuated a pen on a smoked paper chronograph at a central station. This method

FIG. 8.—Hot-Wire Microphone.

involves inevitable errors due to the personal equation of the observer, and is further invalidated by the fact that, in the case of guns, the observer frequently hears only the shell-wave. The difficulties of working from records of this kind have already been discussed. Later, carbon microphones with large wooden diaphragms were introduced, small cells being included in circuit with the microphone and a primary coil, all at the post; the circuit leading back to the recording instrument included a secondary coil wound on the primary. These microphones suffered from the fact that they had a range of sensitiveness similar to that of the human ear; a responded readily to chance sounds, such as the clatter of the ment, or to shaking, and they registered the shell-wave in preference to the gun-wave. They were superseded (first in the British Army, and ultimately in all the Allied armies) by the hot-wire microphone invented by Maj. W. S. Tucker (British patent No. 1312).

and No. 8948 of 1918; see also *Phil. Trans. Roy. Soc., A*, vol. 221, p. 389. This depends on the principle utilized in the hot-wire anemometer, i.e. the change of electrical resistance consequent on the change of temperature of a heated wire which ensues when the air round it is set in motion. A very fine wire of platinum, whose resistance at atmospheric temperature approaches 100 ohms, is mounted in the form of a grid over a circular hole some 7 mm. in diameter (fig. 8). It is provided with terminals. It is included in one arm of a Wheatstone bridge, and sufficient current passed through the network to heat the wire to a dull red. The bridge is balanced so that when the air round the wire is undisturbed no current passes through the galvanometer. Motion of the air causes the resistance of the wire to decrease, upsets the balance, and so causes a current to pass through the galvanometer.

The microphone wire is mounted in front of an air container of some 16 litres capacity. Resonance effects in this container may be partly eliminated by small openings made in the wall. The instrument so completed is insensitive to all sounds of speech, musical sounds, traffic, or even rifle fire. It responds readily, however, to gun sounds (which are low frequency disturbances), even when they are inaudible, and records also the shell-wave. Its reaction is very rapid, and the small lag which does occur appears to be the same for all similarly constructed instruments.

An essential part of the recording instrument is a galvanometer for each circuit which shall respond very rapidly to the current caused by a sound reaching the microphone. For rapid response it is necessary that the moving part of the galvanometer shall be very light indeed—the moving coil or moving magnet type is out of the question. The condition is satisfied by the Einthoven galvanometer, in which the moving part is a very fine wire (through which flows the current to be detected) mounted in a magnetic field. The wire moves in a direction normal to its length and to the direction of the field. Six wires, insulated from one another, and provided with separate terminals, can be mounted side by side in the field produced by a single small electromagnet. This provides in a small space what is essentially six independent galvanometers, one of which is included in the bridge belonging to each microphone. As the sound reaches successively different microphone posts the corresponding galvanometer wires move in rapid response.

The instant at which each wire begins to move is registered on a moving photographic film. The camera in which the film runs vertically is furnished with a horizontal slit, a cylindrical lens in front of the slit reducing its effective breadth. Shadows of the perpendicular galvanometer wires, cast by means of an electric lamp and an optical system mounted in the pierced poles of the galvanometer magnet, fall on the slit, and are focussed on the film, appearing there as six points of shadow on a horizontal line of light. As long as the wires are still each point leaves on the running film a straight line; the movement of a wire registers itself as a break in this trace.

If the film ran at a uniform speed measurement on the developed film of the distance between the breaks would give the required time intervals. As this is not the case the following device is adopted: a wheel provided with ten flat spokes, one of which is somewhat wider than the others, is mounted in the case containing the lamp, so that, when it is rotated, the spokes successively interrupt the light which illuminates the galvanometer wires. The wheel is actuated by a synchronous motor controlled by a tuning fork, and rotates ten times a second. As a result of this arrangement there appear on the film lines perpendicular to the direction of the motion, the intervals between which correspond to hundredths of a second, every tenth of a second being marked by a wider line. This recording apparatus was devised by Dr. Lucien Bull, of the Institut Marey, near Paris.

Originally the film was cut off after the required record had been taken, and developed in a small dark room adjacent to the instrument. Later a method of automatic development was devised, by which the film passed successively through developer and fixer while running, and emerged ready for interpretation.

Fig. 9 shows some typical records. (a) and (b) are records of two differently situated 3.9-in. howitzers taken by six posts in each case. The burst of the shell was also registered on these films, but as it occurs several seconds later space does not permit the inclusion of the part of the record in question. (c) is a record of a field gun, showing both shell-wave and gun-wave. Only five posts were used for this record. The varying interval between the two sounds at the different microphones is well shown: at the flank microphone, corresponding to the lowest trace, only one sound is heard. (d) is a record of the burst of a British shell on a German position.

Influence of Weather Conditions.—The method in use demands that to every time interval shall correspond an exact distance, a standard velocity of sound being assumed, which corresponds to some standard temperature, and still air. (The velocity of sound does not, of course, vary with the pressure, and the effect of humidity is in general negligible.) Hence the time interval read off from the film has to be corrected for temperature and wind before it is used on the board prepared for location. For the temperature variations which occur in ordinary circumstances the increase of velocity of sound may be taken as proportional to the increase in temperature, so that the temperature correction is easily applied. Simple geometrical considerations show that the correction for wind depends only on the velocity and direction of the wind and the position of the microphone,

and not at all on the position of the gun. With given microphone positions a diagram can be prepared which allows the rapid graphical determination of the correction for a known wind.

It has been found by experiment that the temperature and wind which are concerned in these corrections are not those prevailing at ground level, but at a height of between 250 and 500 ft. up.

Owing to the refraction of sound by wind the record of a given sound at ground level is greatly influenced by the variations of wind velocity at different heights above the ground. This wind gradient determines largely whether the conditions are favourable or unfavourable for the detection of sounds. In the case of a wind increasing in velocity with height, a following wind, besides increasing the velocity of the sound, tilts the wave front so that the sound converges on the listener or instrument on the ground, and is well heard. An opposing wind causes the sound to tend to pass upwards and leave the ground. Hence a wind blowing from the instruments towards the hostile piece often renders sound-ranging almost impossible if it be of any strength. The temperature gradient also plays a part in the refraction of sound.

FIG. 9.—Typical records of Bull apparatus.

Location from Record.—Having seen how the intervals between the arrival of the sound at different posts can be accurately obtained and corrected to standard conditions it remains to discuss how these intervals can be made to supply the position of the gun with as little delay as possible. A map board is prepared with an accurate "grid" (coordinate system of squares) covering the region in which locations are expected. On this the microphone positions are accurately marked. The posts are usually taken consecutively in pairs; with each pair as foci a family of hyperbolae may be drawn giving the loci corresponding to various time intervals (at standard velocity of sound). In practice, however, to avoid the labour of preparing the hyperbolae it is usually preferred to use the asymptotes instead of the curves themselves: for these it is only necessary to have a thread attached to each mid-point between pairs of consecutive posts, and a scale plotted round the edge of the board for each base, graduated in time intervals, so that when the thread is placed to pass through a given graduation it is the asymptote to the hyperbola corresponding to the interval. To allow for the divergence of the asymptote from the hyperbola, which becomes serious as the base is approached, tables are prepared giving the corrections (always additive), in terms of the length of the base and the distance from the mid-point of the base, to be applied to the time intervals obtained from the record. The asymptote corrections having been applied to the various intervals, already corrected for temperature and wind, the asymptote corresponding is laid out for each base. The various lines should all intersect at a point: in general they do not, but form a small polygon from which the position of the gun can be estimated.

Estimation of Calibre.—The position of the hostile burst may be obtained from the record of its sound in the same way as the position of the piece, and the interval between the departure and burst of the shell, i.e. the time of flight, can be computed from the record on one microphone. Thus the record gives the time of flight corresponding to a given range, which affords an indication of the calibre of the piece. In the case of guns, as distinct from howitzers, a further indi-

cation can be obtained from the interval between shell-wave and gun-wave at the different posts.

Work in the Field.—It is not feasible to have the film running continuously during any period when records are expected. It should be started a second or two before the sound reaches the first microphone. If the field this is effected by having two forward observers in front of the line of microphones, so placed, one to each flank, that either the one or the other of them must hear the sound of the hostile pie a few seconds before it reaches any of the microphones. These observers are provided with keys, the depression of which starts the film running. They also report by telephone informations judged useful as to the estimated calibre, the approximate location of the burst if seen, and so on.

The line of microphones in general covers a front of some 8,000 yd. and is some 1,000 yd. or more from the front line. It is usually preferred to place the instruments at approximately equal intervals on a smooth curve, which may be a straight line, or the arc of a circle either convex or concave towards the enemy, according as guns well to a flank have to be located, or attention is concentrated on a more central group of guns. Such arrangements lead to greater ease of identification of a record than is possible if the microphones are very irregularly placed.

The microphones may be placed anywhere where the hearing is good: the only obstacles which seem to cast sufficient sound shadow to affect them are high hills just in front of them. They may be put in shallow depressions dug for them, and should be protected from splinters, and also from wind and draughts. Canvas and hurdles may be used for the latter purpose without appreciably affecting the sensitiveness of the instruments.

Ranging on the Pieces.—A heavy burst near a hostile gun position will furnish a sound record of its position just as does the gun itself. Fire may be directed on a piece which is in action by comparing the records which it supplies with those of the bursts of one's own answering shell. Since both gun and burst are located by the same method of uncertainties introduced in an ordinary location by ignorance of the precise atmospheric conditions are eliminated.

A differential method is adopted, the difference of times of arrival of the sound of the hostile gun and of the friendly burst at each microphone being plotted as ordinates against a certain simple function of the relative positions of the microphones and the hostile gun as abscissae. A horizontal line then corresponds to a direct hit; a straight line sloping to left or to right to an error of line to one side or the other; a curve (approximately an elliptical arc) convex or concave downward to an error of range. The magnitude of the corrections necessary is easily estimated from curves previously prepared.

RANGER, HENRY WARD (1858-1916), American painter (see 22.891), died in New York City Nov. 7 1916.

RASPUTIN, GREGORY EFIMOVITCH (1871-1916), Russian monk and court favourite, was born in 1871 in the village of Pokrovskoe, near Tyumen, in the province of Tobolsk, Siberia. He was the son of a poor peasant whose disorderly behaviour resulted in his being given the name of Rasputin, meaning "debauchee." He received no education, and till the end of his life was unable to write properly. He spent the first part of his life till the age of 33 in his native village; he married in 1895 a well-to-do girl, Olga Chanigoff, and they had two daughters and a son. In 1904 Rasputin resolved to change his mode of living. He left his family and devoted himself to religious exercises, declaring to his people that he was inspired by God. His passionate nature, his great physical strength, and the superstitious atmosphere in which he had been brought up, gave an unexpected direction to his religious exaltation. He adopted the views of the sect known under the name of "Khlysty," the leading idea of whose teaching was that salvation could be achieved only by repentance.

"Sin in order that you may obtain forgiveness"—was the practical rule which he drew from this doctrine. "A particle of the Supreme Being is incarnated in me"—he told his hearers. "Only through me you can hope to be saved; and the manner of your salvation is this: you must be united with me in soul and body. The virtue that goes out from me is the source of light, the destruction of sin" (E. J. Dillon, *The Eclipse of Russia*). This extravagant and dangerous teaching, which resulted in practice in the most wild orgies, not only created for Rasputin immense popularity and the reputation of a holy man among his fellow-peasants, but opened before him the doors of some of the most fashionable Russian houses and even those of the Imperial Palace. Looking for new experiences Rasputin left his native village, and made long pilgrimages to various holy places, and even went to Mount Athos and Jerusalem. He spent some time in

different monasteries and applied himself to the study of holy books, but his lack of elementary education reduced the results of his labours almost to nothing. He only retained by heart some incomprehensible passages, and often used them in his prophecies. He had, however, a strong magnetic power, the influence of which was recognized by his bitterest opponents.

In 1907, during a stay in St. Petersburg, Rasputin was introduced to the Archimandrite Feofan, rector of the Theological Academy and confessor to the Empress, who took an interest in the story of his conversion. The Archimandrite, with the assistance of the Grand Duchesses Miliza and Anastasia, presented Rasputin at court, and he produced a deep impression on the Empress and Emperor. The mystic atmosphere which always prevailed at the Russian court, and which was especially strengthened by the disasters of the Japanese War, the internal troubles in 1905, and the constant fear for the health of the Tsarevich, created a convenient background for the appearance of such a man. His disdain for all rules of good behaviour, his dark prophecies, and, above all, the eventual improvement in the health of the Grand Duke Alexis, which more than once seemed to result from his influence when medicine was ineffectual, created an exceptional position for him with the Empress. Disgusted with the Russian intellectual classes and the bureaucracy, she saw in Rasputin the representative of the mass of peasantry, the only sure support of orthodoxy and autocracy, specially sent by God to save the heir to the throne and preserve the dynasty. Rasputin took advantage of this belief, and did his best to persuade the Empress that his fate was closely tied with that of the imperial family. The example of the court was followed by a large section of the upper class, and many doors were opened for the "Saviour," as the Empress used to call him. For some time Rasputin was satisfied by this side of his social success, and at first he did not interfere in politics. But his activity was felt in church questions. His friendship with the famous monk, Heliodor, and the Bishop of Saratov, Hermogen, which resulted in a complete rupture between them and in a series of scandals, had a painful echo in the country. The appointment of Varnava, an illiterate peasant and a friend of Rasputin, to be Bishop of Tobolsk in 1911, and the extraordinary servility with which the Holy Synod followed the wishes of the favourite, provoked a strong opposition among all classes of society. The most prominent upholders of orthodoxy demanded a complete reorganization of the Russian church, and denounced the servile attitude of the Holy Synod. Guchikov, the Octobrist leader, in a famous speech delivered at the State Duma, made direct allusions to the nefarious influence exercised by Rasputin. But the influence of the "Saviour" was too strong to be checked by any expression of feeling in the country, and Rasputin triumphed over all his enemies.

An unsuccessful attempt to kill him, made by a certain Guseva in 1914, incited by the monk Heliodor, only strengthened his influence, which became especially powerful during the two last years of the imperial regime. No important nomination was made without his approval, and the most unexpected people rose to the highest offices as result of his interference. Rasputin was too ignorant to have any opinion on political questions: he was in most cases an instrument of the reactionaries. Numberless stories of the debauchery practised at the court, in which the name of Rasputin was coupled not only with some of the court ladies but even with that of the Empress herself, became a common topic of conversation in all classes of Russian society. At length a supreme effort to free the Empire and the dynasty from his influence was made by a small group of men of the highest social position, which included the Grand Duke Dimitri Pavlovich, Prince Yussupoff and M. Purichkevich. Rasputin was invited to a supper at the Yussupoff Palace on Dec. 15 1916, and shot dead, after an attempt at poisoning him with a strong dose of cyanide potassium mixed with wine had not produced the desired effect. His body was thrown under the ice of a canal. The death of Rasputin was a terrible shock to the Empress; she transferred his body to the park of Tsarskoye Selo, where a special chapel was erected, and came every night to

pray on his grave. The Grand Duke Dimitri Pavlovich was sent to Persia to join a fighting column. Yussupoff was ordered to leave Petrograd, and interned in his estate. Purichkevich, protected by his immense popularity in the army and by his title of member of the Duma, returned to his work on the front.

(P. VI.)

RATHENAU, WALTER (1867–), German industrialist and political economist, president of the Allgemeine Elektrizitäts-Gesellschaft, was born Sept. 29 1867 in Berlin. He came into prominence in Aug. 1914 as the founder and director of organizations for providing raw materials, during the World War, for Prussia and the German Empire. On the formation of the Warth Ministry in May 1921 he was appointed Minister of Reconstruction, and in that capacity negotiated with the French minister, Loucheur, a convention for supplying German materials for the restoration of the devastated area in France, and thus paying in kind part of the reparation which the German Reich had undertaken to pay in gold. Rathenau published various books, pamphlets and articles, on social and economic questions, some of which attracted world-wide attention, especially his *Von kommenden Dingen* (1920). In Jan. 1922 he became Foreign Minister in the Warth Ministry.

RATHMORE, DAVID ROBERT PLUNKET, 1ST BARON (1838–1919), Irish lawyer and politician, was born Dec. 3 1838, the third son of John, 3rd Baron Plunket (1793–1871). He was educated at Trinity College, Dublin, taking his degree in 1859, and was called to the Irish bar in 1862. He was made Q.C. in 1868, and the same year became legal adviser to the Irish government. In 1870 he stood successfully as Conservative member for Dublin University, holding the seat for twenty-five years. From 1874 to 1877 Plunket was solicitor-general for Ireland, and in 1880 was for a short time paymaster-general. In 1885 he was first commissioner of works in Lord Salisbury's ministry, and resumed this post in 1886, when the Conservative party returned to power, holding it till 1892. In 1895 he was raised to the peerage. He died at Greenore Aug. 22 1919.

RATIONING.—In the articles **FOOD SUPPLY** and **SAVINGS MOVEMENT** the general question of food control during the World War is dealt with. During 1914–8 most of the European states, belligerent and neutral, were driven, by shortage of supplies, to ration the consumption of the more important foods, and in some cases of other articles, by the civilian population. "Rationing," of course, is a term of military origin; it denotes the supplying to each member of a fighting force or a beleaguered population of a definite "ration," based upon calculation of his needs, of the supplies available, and of the period for which they must serve. The process of rationing, therefore, has two sides—negative and positive: the negative side of preventing any individual from obtaining, by purchase or otherwise, more than the authorized quantity of the rationed article, and the positive side of making it possible for each individual in fact to obtain that quantity. It is thus a problem both of restriction and of distribution, and the success of any rationing system may be judged even more by the degree to which the positive side is carried out, than by the completeness with which the prohibition upon excessive consumption is enforced.

In this respect the British system of food rationing had for the reasons mentioned below a relatively high measure of success and is therefore described here in some detail. The modified system adopted in the United States is dealt with in a final section. Besides food and feeding stuffs for animals, fuel and light were rationed in the United Kingdom, and both these and many other things, such as clothing, tobacco, matches and housing accommodation, were rationed in various enemy and neutral countries in Europe.

BRITISH FOOD RATIONING

Historical Sketch.—The earliest steps to the introduction of compulsory rationing in Great Britain were taken in relation to sugar. Since the first month of the war sugar had been subject to Government control, under a Royal Commission on the Sugar Supplies, constituted in Aug. 1914. By the end of

1916 the quantity of sugar that could be obtained for the United Kingdom as a whole began to fall far short of the public demand, and in the first part of 1917 this reduced quantity was being distributed on the basis of giving so far as possible to each trader, whether wholesale or retail, 50% of the quantity which he had received in 1915, it then being left to the retailer to divide his supplies as best he could among his customers, subject to a limit of price. This simple system was necessarily very imperfect in action, and grew steadily less satisfactory owing to changes in the distribution of the population. With the development of the munitions campaign new towns sprang up as at Gretna or Birtley; old towns like Coventry or Sheffield or Woolwich doubled or trebled their population or acquired new suburbs; from many country districts and provincial or university towns in the south of England the population ebbed away. Distribution of sugar or any other article of food on the 1915 basis became manifestly inequitable.

During the first half of 1917, while the acute difficulties of the new munition areas were being relieved by temporary palliatives, such as the dispatch of additional supplies after enquiry by inspectors in each case, schemes for recasting the whole system of distribution on the basis of a complete free registration of the population were worked out and several alternative schemes were submitted to the War Cabinet in June 1917. The Cabinet adopted one of the alternatives, under which each household was to be invited to register for sugar with a particular retailer, to whom supplies of sugar would be sent in accordance with the numbers and size of the households registered with him, at a specified ration per head, but under which there would be nothing to prevent a retailer from using any surplus sugar in his hands to supply others, or to prevent persons from getting sugar, if they could, in excess of the ration, or from any retailer other than the one with whom their household was registered.

The scheme, while applied in the first instance only to sugar, involved the setting up of extensive administrative machinery, which could thereafter be used both for rationing other foods and for any other local work of the Ministry. This machinery consisted in essence of some 1,800 Food Control Committees appointed by the local authorities, but with their expenditure met from national funds, together with Divisional Food Commissioners appointed directly by the Ministry of Food for the 15 main divisions into which the country was divided, and having the special function of supervising, assisting, and coördinating the work of the committees. Immediately after the presentation of these proposals to the Cabinet (June 1917) the first food controller, Lord Devonport, resigned his office, and the proposals were approved by the Cabinet, subject to their receiving the subsequent assent of his successor, Lord Rhonda. The latter did in fact assent, and proceeded at once with the schemes both for redistribution of sugar and for divisional and local organization. The 1,800 local sanitary authorities in Great Britain were invited by Circular (issued Aug. 2 1917) to appoint Food Control Committees, and did so during Aug. and the first part of September. Each committee set up a local "Food Office," usually in one of the municipal buildings, appointed an "Executive Officer," and during Sept. and Oct. issued to each household in the district a sugar card showing the number of persons in the household, and having a counterfoil to be detached and deposited with the retailer from whom the householder proposed to get his sugar. There was thus carried out a complete registration of the population by households in each district. The intention was to bring the distribution of sugar to each district on to the new (population) basis, as opposed to the old (1915 trade) basis as from Jan. 1 1918.

The sugar scheme, however, was never brought into force in the form approved by the Cabinet. In that form it was a distribution not a rationing scheme, was based on households not individuals, and deliberately made no formal provision for transfer of individuals from one household to another, or for persons too migratory to form part of any household. An alternative scheme for rationing by means of individual cards, entitling the holder to a fixed quantity and no more, had been

submitted to the Cabinet in June 1917 but was rejected, because at that time the Cabinet was not prepared for rationing as such. It seemed doubtful whether the public would submit to compulsory restriction of their food consumption; there was further an objection to giving the enemy the encouragement of seeing Britain apparently driven to extremities by the success of the submarine campaign.

By the end of Sept. it became clear that the public were prepared and anxious for definite rationing, that is to say for a system under which nobody could get more than a certain quantity and everybody could be certain of getting that. In Oct. and the following months accordingly the scheme was entirely revised and provision made for the household sugar cards to be exchanged for individual cards, and for any person who belonged to no household to obtain a document which should be the sole title to sugar supplies.

Another and more drastic change was also contemplated, namely, the substitution of a single centralized register of sugar consumers, that is to say of the whole population, for the 1,800 separate local registers which had resulted from the registration of households under the original scheme. The first steps to the formation of this central register—in the Imperial Institute buildings at South Kensington—were taken in Nov. 1917, and a good deal of preliminary work was done. The change over from local to central registration, however, was only to be made gradually, and was in fact never completed. After the success of the schemes described below—for rationing fats and meat on the basis of local registration (Feb.-April 1918), the idea of making a central register of the population was abandoned. The public, though at times mildly puzzled by the changes of the cards with which they had to deal, remained for the most part unconscious of the successive revolutionary changes in the ideas which dominated the administration of rationing.

The scheme, which had been started as one for the distribution of sugar to households in July 1917, came into force as a scheme of rationing by individuals on Jan. 1 1918 without a hitch. The reserve stocks at the disposal of the Sugar Commission were at that time considerable, and, since sugar is not highly perishable, the Commission had been able to distribute those stocks widely and to provide each retailer with an ample margin to meet contingencies. With insignificant exceptions, every person in every part of the country was able from the outset to get week by week the ration of half a pound of sugar to which his ration document entitled him.

Meanwhile, in the last quarter of 1917, the public became aware of serious shortages of other commodities, in particular tea, margarine, bacon and cheese. These shortages led to the appearance of queues at the shops and threatened to arouse grave industrial unrest. The centralized rationing scheme which was then the accepted policy in London could not come into force for many months. On the other hand the Food Control committees were established and at work; it was natural for Lord Rhondda to ask the committees to deal with the difficulty of the queues in the interim as best they could. One or two of the committees, among whom the Birmingham committee was conspicuous, started their own schemes for registering consumers with retailers and controlling the distribution of supplies to the retailers by the exercise of powers of requisition granted by the Ministry. General provision for such schemes was made by an Order of the Food Controller of Dec. 22 1917, which was called a Food Control Committees (Local Distribution) Order, but was in fact an order authorizing committees to introduce complete local rationing of any or every article, subject to approval of the scheme by the Ministry of Food. An important memorandum issued to the committees on Dec. 29 1917 outlined model schemes and gave advice and suggestions. The formulation of local schemes in congested industrial areas at once showed the impracticability of purely local action. It was clearly impossible for several Food Control committees in neighbouring districts forming part of a single industrial town to have different rationing systems, or for some to ration while the others did not. It was equally impossible for local committees

to control the distribution of foods, such as frozen meat or margarine, which are stored or manufactured at a few main centres for distribution throughout the country. These difficulties came to the fore at once in London and its suburbs.

At a general meeting of executive officers of the London committees held on Jan. 4 1918, it was resolved to have a single rationing scheme for the whole Metropolitan area and to ask the Ministry of Food to prepare such a scheme for approval by the committees as a whole. It became clear almost immediately that no convenient break could be made between London and the districts immediately surrounding it, and the home counties were included. The scheme was originally asked for to deal with fats (margarine and butter) alone, but the meat shortage became acute at a moment's notice in Jan.; and estimates of the quantities available in the first quarter of 1918 made it imperative to include meat as well.

A scheme covering both fats and meat was worked out accordingly by the Ministry, approved at another meeting of executive officers, embodied in a "London and Home Counties (Rationing Scheme) Order," and brought into force on Feb. 25 1918 for an area containing something like 10,000,000 people. It involved the issue of two ration cards to each individual, one with detachable coupons for meat, and one for butter and margarine, without coupons, but with numbered spaces in which the retailer marked off the customer's purchases as they were made; each card had a counterfoil to be deposited with a retailer, and the supplies were distributed to retailers on the basis of the counterfoils deposited with them. The scheme had an almost melodramatic success. The London queues, which, according to the observations made by the Metropolitan Police, had included, in each of the weeks just before rationing, over 1,300,000 people, fell to 191,000 in the first week and to 15,000 in the fourth. Before rationing about 550,000 persons stood in food queues every Saturday in London; on the first Saturday after rationing the number was 110,000, on the next 24,000, and on the fourth Saturday under 7,000. In effect the queues for meat and fats disappeared altogether; there remained only queues for cheese, jam and other unrationed articles. The success of rationing was one of organisation; the total amount of meat and fats available for consumption and actually consumed in London was not greater after rationing than before. It was simply better distributed and made obtainable without the labour of standing in a queue.

Meanwhile local schemes under the Order of Dec. 22 1917 had made considerable headway in the diminution or abolition of queues for butter and margarine outside London and the home counties. The local rationing of meat, however, presented insoluble difficulties, and even before the introduction and success of the London scheme the decision had been taken to introduce a national scheme for meat rationing as soon as possible. This was done on April 7.

The extension of meat rationing to the whole country was as successful as its introduction in London. The queues disappeared and everyone everywhere got his ration. This result decided incidentally the fate of the sugar scheme. The attempt to form in London a central ration register of the population was abandoned; the staff, till they could be dispersed, were used on other work in the checking of coupons, and arrangements were made to include sugar in the uniform scheme of national rationing through local committees which was introduced on July 14 1918, when each member of the public received a single book with different coloured leaves of uniform coupons for meat and bacon, fats, sugar, and lard. These, with jam included for the first time in Nov. 1918, were the only articles of food which were rationed nationally, i.e. throughout Great Britain. In addition tea was rationed in most of the great industrial centres under local schemes, and came within an ace of being included under the national scheme of July 1918. Cheese was rationed by a number of committees, but the varying consumption in different parts of the country and by different classes of consumers made any uniform system difficult; it continued to the end to be distributed on a "trade basis," that is to say by giving

to each trader a fixed percentage of his supplies in a datum year. Tea, on the other hand, though never rationed nationally, came to be distributed on a registration basis, i.e. in accordance with the actual population in 1918. In addition to articles for human consumption, feeding stuffs for animals were also controlled by the Ministry of Food, and in the latter part of 1918 were brought under a formal rationing system; this system hardly had time to come into full operation when the war ended.

The first national ration book had a currency of 16 weeks, and was succeeded by a fresh issue with no material change except an extension of currency to six months on Nov. 4 1918. After May 3 1919 coupons were abolished, but a limited system of rationing without coupons, by means first of the old ration books and later of identification cards, was continued for many months. Bacon and ham were freed from rationing in July 1918, lard in the following Dec., margarine in Feb. 1919, jam in April 1919, and meat in Dec. 1919. With the freeing of butter in May 1920 and sugar in Nov. 1920 rationing came to an end.

The foregoing sketch applies only to Great Britain. No rationing of meat or fats was attempted in Ireland, but a sugar distribution scheme, on the lines of the first British scheme, was put into force in Ireland by the Irish Food Control committee under powers conferred by the Food Controller.

National Rationing Scheme.—The Rationing Scheme, as finally established in July 1918, was a uniform national system administered by autonomous local committees, and having as its main features the use of individual ration books, the tie of each customer to a particular retailer, and the systematic supply to each retailer of the quantities required to meet the needs of his registered customers. A single application form had to be filled in by each household and forwarded to the Food Office, which thereupon issued a separate ration book for each member of the household. The ration book was a book containing different coloured leaves for various foods. Each leaf consisted of (a) a counterfoil to be signed, detached and given to the retailer with whom the holder of the book wished to register, and (b) coupons for each week's supply to be detached by the retailer when actual purchases were made. On registration of the customer the retailer besides detaching the counterfoil was required to enter his name and address on the appropriate part of the ration book. In addition to the leaves for foods rationed, such as sugar or meat, there were spare leaves which could be used for rationing other foods at short notice, and one of these was in fact adapted to deal with bread should the occasion ever arise. The book contained also a reference leaf, which served as an application form for subsequent issues. There were special books for children under six years of age (who got half rations of meat), books authorizing supplementary rations of bacon for manual workers and growing boys, and special books or leaves of coupons for invalids, travellers, vegetarians, Jews, soldiers and sailors on leave, and other particular classes.

The tie of each customer to a particular retailer was the essence of the scheme, the main safeguard against fraud, and the basis of distribution. Behind rationing as the public saw it—a paper affair of application forms, counterfoils and coupons—was a not less extensive and intricate machinery for distribution of the appropriate supplies through all the complex channels of trade week by week to every retailer in the country. The precise form of this machinery was naturally different for different articles of food; the common feature in all cases was that the retailer had to make an indent on a wholesaler in accordance with the number of persons registered with him, and each wholesaler in turn made application to a primary supplier (manufacturer, importer or other) based upon and accompanied by copies of the retailer's indents. The supplies flowed downwards through the various channels of trade in accordance with the applications and indents. The retailer's indents had in some cases to be approved in advance by the Food Control committees; in all cases their correctness was liable to be checked by examination of their registers of customers and of the counterfoils detached from the ration books.

In the case of meat, where the civilian supplies were mainly homegrown, there was needed in addition an elaborate organization, under Livestock Commissioners appointed by the Ministry of Food, for controlling the bringing of beasts to market, and their slaughtering and distribution, and for supplementing home supplies from the reserves of imported meat. In the case not only of meat, but of butter and margarine, there was a further difficulty—that the food was highly perishable and the retailers could not carry reserve stocks.

The importance of the tie to the retailer became apparent when it came to be realized that it would be perfectly possible to have a rationing scheme without coupons at all, if every individual consumer had to register at a particular shop and the supplies to that shop were adjusted strictly to the registration. The value of the detachable coupon was, first, in enabling the retailer to know whether he had already given a particular customer his supply for that week, and second, in affording a check upon the retailer, who could be required to make returns of supplies received, sold or retained, and to account for the supplies sold by producing an equivalent number of coupons. The staff collected for central rationing was used from April 1918 onwards to check the retailers' accounts by counting the coupons they had collected.

Apart from the points mentioned the technical details of most importance in the rationing scheme were the following:—

(1) The fixing of the ration for uncooked butcher's meat by value rather than by weight. Under the London scheme and the general meat scheme of April 1918 each card had for each week three coupons entitling the holder to buy 3d. worth per coupon, i.e. 1s. 3d. worth altogether of uncooked butcher's meat. As the price per lb. for each cut of meat was regulated by an elaborate schedule having regard to quality, to proportion of bone and to other matters, the fixing of the ration by value afforded an automatic means of adjusting the ration according to the cut selected. This device proved quite satisfactory and was continued in all subsequent schemes.

(2) The classification of "establishments," ranging from prisons and asylums to schools, hotels, living-in establishments, tea-shops and seaside boarding houses. With the single exception of the problem of the "self-supplier" this is technically the most difficult part of rationing, and the relatively efficient treatment of establishments in the British system was a considerable element in its general success. It is probably true to say that Britain was the only European country which made serious inroads on the comfort of living in first-class hotels or lunching at first-class clubs during the war.

(3) The provision for transfers of registration from one retailer to another, or from one district to another. This part of the scheme was framed with considerable care; the widespread organization of the Food Control committees bringing a food office within easy reach of every considerable number of inhabitants, and the reasonable latitude allowed to their officers in dealing with local and personal emergencies, prevented registration formalities from becoming intolerable.

The problems of "self-supply" and "direct supply," i.e. of persons producing food for themselves or obtaining food direct from the producer and not through a trader, arose in Great Britain only to a limited extent, and cannot be said to have been fully solved. Restrictions were imposed but were not pressed to the utmost.

The articles rationed and the amounts allowed at various dates are set out in the appended table.

Comparison with Other Countries.—The problem of rationing was simpler in Britain than in most European countries, and far simpler than in Germany and Austria, for the following main reasons: first, the deficiency of supplies below normal was less; second, the bulk of the British supplies were imported, not home-grown; third, the supplies of cereals could be and were kept at a point high enough to allow rationing of bread stuffs to be avoided altogether.

The difference in supplies is clearly illustrated by a table given in the article FOOD SUPPLY and published by the Ministry

of Food at the end of 1918, comparing the estimated consumption per head of certain essential foods in the United Kingdom, Germany and Holland before and during the war. Another striking contrast emerges in the report of a committee appointed at the Ministry of Food at the end of 1917 to prepare a comprehensive scale of rations covering meat, cereals, fats and

Rationing in Great Britain 1917-20.

Article.	Period of Rationing (whether local or national).	Amount of Weekly Ration per Head.
Sugar	Nationally—from Dec. 31 1917 to Nov. 29 1920	8 oz. Dec. 31 1917 to Jan. 27 1919; there-after sometimes 12 oz. and sometimes 8 oz. with a drop to 6 oz. for a few weeks in Sept.-Oct. 1919, and again Jan.-March 1920.
Butter and Margarine	Locally from Dec. 14 1917 to July 1918 (38,000,000); there-after nationally to Feb. 16 1919 for both fats, and to May 30 1920 for butter alone.	5 or 6 oz. for both fats under national scheme. The London scheme started with a ration of 4 oz. The separate butter ration after Feb. 1919 varied from 1 to 2 oz.
Lard	Locally from Jan. 1918 (1,500,000); nationally from July 14 1918 to Dec. 16 1918.	2 oz. nationally and in most local schemes.
Meat (Uncooked Butcher's Meat)	London and home counties from Feb. 25 1918 (10,000,000) with a few other local schemes; nationally from April 7 1918 to Dec. 15 1919.	Under the London Scheme 3 coupons entitling to 4d. worth each, or 1s. altogether (about 1 lb. with average bone), subsequently changed to 1s. 3d. Under the national scheme varying values as follows: 1s. 3d., 1s., 1s. 4d., 1s. 8d., 1s. 4d., 1s. 8d., 2s.
Bacon and Ham.	London and home counties from Feb. 25 1918 (10,000,000) with a few other local schemes; nationally from April 7 1918 to July 29 1918.	Under the London scheme 4 oz. with bone per coupon. Under the national scheme 5 oz. and 8 oz.
Other Meats	All meat (including preserved meat, poultry, game, offal, venison and horse-meat) was included in original London scheme, but control was gradually relaxed.	Varying rations.
Jam	Locally from early part of 1918 (500,000); Nationally from Nov. 4 1918 to April 15 1919.	4 oz. under national scheme.
Cheese	Locally from early part of 1918 (2,000,000).	1½ oz. to 2 oz.
Tea	Locally from Dec. 1917 (17,500,000).	1½ oz. to 2 oz.

Notes.—The numbers in parentheses give the maximum numbers covered by local schemes of rationing. The number covered by national rationing, i.e. the civilian population of Great Britain, in 1918 was 39,000,000.

In the London scheme and the first national meat scheme (April 7 1918) four coupons were provided to cover all meat of every kind. Three of these coupons only might be used for uncooked butcher's meat; any of them could be used for bacon, poultry, preserved meat, etc. The normal ration at the outset was thus 1s. worth (=½ lb. with average bone) of uncooked butcher's meat, together with 4 oz. of bacon with average bone, or in place of the bacon, varying quantities of offal, poultry, game, etc. Later the rations were raised.

sugar. The committee based their scale on estimates of the minimum numbers of calories per day required by various classes of persons, according to age and occupation, and of the proportion that, having regard to other foods available, should be provided by these essential foods. Comparing their scale with the actual rations in force during 1917 in Hamburg (taken as typical of German industrial conditions), the committee found that the latter scale represented in respect of these essential foods and potatoes not more than ½ of the minimum requirements, while the shortage of less essential foods was probably even greater. The German ration of fat was reduced still further as from Jan. 1 1918, making the Hamburg rations per week for ordinary adults as follows:—Bread 4½ lbs.; Meat 9 oz.; Fats 2½ oz.; Sugar ½ lb.; Potatoes 7½ lbs. Men engaged in physical labour received a supplementary ration of 1½ lbs. of bread (per week), and those engaged in exceptionally hard physical labour received altogether 7½ lbs. of bread, ½ lb. of meat, 4½ oz. of fats, ½ lb. of sugar and 9½ lbs. of potatoes. These men would be few in number.

The weekly rations in Vienna by the end of 1918 were even lower:—Bread 2½ lbs. (with an additional 2 lbs. for heavy workers); Meat 4½ oz.; Fat 1½ oz.; Sugar nil, and Potatoes 1½ lbs.

The Austrian figures represent a breakdown of supplies and society. The German rations are those on which the civilian population of Germany sustained the war and made munitions during 1917 and 1918. They show a power in the human body to endure over months and years, at whatever cost in permanent loss of health and vigour, a scale of nutrition far below the minimum prescribed by scientific authority. They indicate at the same time the intensity of the strain to which the rationing regulations of the enemy countries were subjected.

The advantage to the British food controller in obtaining so large a part of his supplies from overseas was equally decisive. Imports were all brought automatically and completely under public control; nothing remained save distribution and the fixing of prices. The German and Austrian food controllers had to rely almost exclusively on home-grown supplies; they were faced by and failed to solve the problem of obtaining from the home producers a fair proportion of their produce for distribution under the rationing system. To a small extent this fact must be taken as a correction of the previous statement of rations as showing the actual consumption; an appreciable part of the total supplies escaping public control altogether was sold as contraband (*Schleichhandel*) to the urban consumers. The actual consumption in each family was the ration plus a varying proportion of contraband. The contraband trade, however, in Germany at least cannot have benefited more than a small proportion of the industrial population and was mainly an advantage to the well-to-do and to the hotels. It had a disastrous reaction on the general respect paid to the rationing regulations, and deprived them of that support of public opinion which was so marked in Great Britain.

The third great advantage of the British food controllers was that, by securing adequate tonnage for cereals, they were able to avoid the rationing of bread stuffs, and the elaborate and contentious system of graduated rations for different classes of workers which would otherwise have been inevitable. So long as rationing is confined to articles other than bread, a flat scale of rations for all adults, whether engaged in sedentary or in severe physical work, is possible; the larger amount of calories which the latter classes must have, in order to perform their work, can be obtained by increasing their consumption of bread. If bread as well as meat, fats and sugar are rationed this individual adjustment of consumption, according to the physical energy required, becomes impossible. The rationing system itself must provide differentiated rations for men doing varying kinds of physical labour or doing little or no physical work at all.

All the continental countries which rationed bread-stuffs had accordingly to introduce "supplementary" rations for heavy workers of different grades; the classification of the population for this purpose was one of the most difficult and contentious

parts of the whole system; it appears to cut at the root of the principle of equality upon which rationing is based. In Great Britain a scheme of supplementary rations of bacon, for growing boys and for men engaged in physical labour, was introduced in April 1918, not so much for its own sake as in order to get the recipients classified, and so to prepare the ground, in case bread rationing became necessary, as at that time appeared possible. Fortunately the danger to the British bread supplies passed over; the supplementary rations of bacon, though they received the general support of the Food Control committees and were clearly right in principle, were strongly criticized by labour representatives, and were abolished when bacon was freed from rationing in July 1918.

While for the three reasons stated it must be recognized that the British rationing problem was immeasurably simpler than the German or the Austrian one, it may still be claimed that even allowing for this the British system was definitely superior in itself. First, the proper balance between centralization and decentralization of responsibility was attained. The British system was national and therefore uniform and fair in principle, but was carried out by local authorities with ample power to adjust it to local conditions. German rationing was local in origin; the central authorities had the impossible task of securing co-ordination subsequently; the traveller from one part of the country to another found himself under different regulations in every town. Second, the British food controllers never issued a ration book without a distribution system to back it. Third, the British system was probably superior in the ingenuity of many technical details. In respect of one of the main articles of food, namely meat, the British like the German controllers had practically to rely upon home-grown produce for the civilian population and had the same problem of collecting supplies from the producer. Fourth, and finally, the British system was more successful in giving equal treatment to rich and poor. This was its corner stone. Lord Rhondda had many doubts as to the practicability of rationing. He feared that the public would never submit to being limited in their purchases, tied to one retailer and subjected to transfer formalities every time they moved from one district to another. He found that the British people in war were prepared to submit to any and every restriction on their freedom of action so long as it applied fairly to all alike.

(W. H. B.)

UNITED STATES

Food rationing, properly speaking, was resorted to in the United States during the World War only in a modified form, and as to two commodities, wheat flour and sugar. That is to say, the rationing system under which a strict limit was set by law and regulation to the amount of food any person might purchase, as was the case in European countries where the rationed foods were issued only on presentation of official food cards, was practically unknown in the United States. The food saving there was accomplished in general as explained in the articles *FOOD SUPPLY: United States* and *SAVINGS MOVEMENT: United States*, through the voluntary self-denial of citizens in response to Government appeals and recommendations.

Sugar.—In the last three months of 1917 a serious shortage of sugar developed, and American householders, particularly in the eastern states, had difficulty in obtaining even small quantities for table use. This shortage emphasized the necessity for special attention to its conservation. As a first step, manufacturers of "soft" drinks, candy and related commodities, were directed to reduce their consumption to 80% of the amount used by them during the first six months of 1917. This attempt at conservation was not wholly successful in its operation as some of the less patriotic manufacturers ignored the direction. On May 15 1918, when the urgent need for shipping had resulted in a diversion of tonnage from traffic with Cuba to longer voyages, regulations were issued requiring that sales of sugar to manufacturers of the less essential foods and drinks should be made only upon presentation, by these manufacturers, of certificates which they were required to obtain from the federal food administrator of the state. These certificates were issued only upon proof that the applicant had not used since Jan. 1 1918, 80% of the amount of sugar used by him in the first half-year of 1917, and the certificate enabled the manufacturer to obtain only enough sugar to bring his total to this 80 per cent. The sugar shortage became still more serious, and with the prospect of a repetition of the ex-

perience of the fall of 1917, a rationing plan modelled upon certain European systems was put in force beginning July 1 1918. The refiner or manufacturer of sugar was forbidden to ship sugar to a purchaser except upon the receipt of a certificate issued by the federal food administrators. These certificates were issued to retailers on the basis of the number of their customers. Customers were allowed to purchase only on the basis of 1 lb. per person per month. This was increased to 2 lb. on Oct. 15 1918, and the restriction was removed in Nov. 1918. The local administrators were also authorized at all times during the home canning season to issue certificates permitting housewives to buy sugar in 25 lb. lots for canning purposes after the giving of satisfactory proof that it was desired for such purposes. A further regulation for manufacturers using sugar divided them into classes, with respect to the necessity for their products, and they were permitted to buy only on the presentation of certificates issued to them on the basis of their classification. Comparing the figures for war-time consumption of sugar in the United States with pre-war and post-war consumption, a saving of from 400,000 to 600,000 tons is shown to have been accomplished through conservation measures. Assuming it to have been 500,000 tons, it would have supplied people in France for a year, at their ration of 35 lb. per head.

Wheat Flour.—In addition to the appeals for voluntary conservation, which were particularly stressed with reference to wheat flour, compulsory regulations were put in force as to certain dealers and distributors of this commodity in Jan. 1918. This step was determined upon as a result of a particularly serious appeal addressed in that month to Mr. Hoover by Lord Rhondda, British Food Controller. Lord Rhondda cabled that unless the United States could furnish 75,000,000 bus. of wheat by July to the Allies, he could not be responsible for their remaining steadfast in the war. Accordingly flour mills were required to raise their percentage of extraction to 74% and to eliminate altogether the sale of patent flours. On Feb. 3 1918, the bakers were required to use 5% of substitute flour in all bread, and this amount was raised to 20% on Feb. 24 and on May 3 to 25 per cent. Rules were also promulgated early in 1918 requiring manufacturers of cake, breakfast cereals, macaroni and the like to limit their consumption of wheat flour to 70% of the amount they had used in 1917 for the same purposes. Since more than 50% of the flour consumed in the United States is used in home baking, it was necessary to require housewives as well as bakers to use substitutes for wheat flour. Regulations were accordingly issued, about Feb. 1 1918, requiring that no dealer or miller should sell wheat flour to an individual consumer without an equal amount of substitutes. The substitutes specified included all substitute flours, corn meal, corn grits, oatmeal and rice. Although this was not, strictly speaking, a rationing measure, it is estimated that it accomplished a saving of approximately 25% in the household consumption of wheat flour. Notwithstanding a shortage instead of a surplus at the beginning of the year 1918, the American people saved out of their own consumption sufficient wheat to send to the Allies, between Jan. 1 and the harvest, not merely the 75,000,000 bus. for which Lord Rhondda pleaded, but a total of 85,000,000 bushels.

The rationing measures described were withdrawn in Nov. 1918, and after that date there was no governmental limit upon the purchase for consumption of any food commodity in the United States. Although a sugar shortage developed there in 1919 as a result of the continuing world shortage, no revival of control over consumers' purchases was attempted in the United States. The Sugar Equalization Board, which had been continued in existence for distribution of the 1919 crop, revived, for a short time and to a limited extent, its control over distribution by directing to what sections of the country refiners should ship their product. The fact remains, however, that such rationing measures as the U.S. Government employed were in force only for a few months in 1918.

(W. C. M.)

RAVEL, MAURICE (1875–), French musical composer, was born at Ciboure, France, March 7 1875, and received his musical education at the Paris conservatoire, under Fauré, Pessard and Bériot. His compositions include, besides songs, piano-forte music, and chamber music, the *Schéherazade* overture (1911), *Rhapsodie Espagnole* (1907), and the one-act opera *L'Heure Espagnole* (1907), first produced at Covent Garden in 1919.

RAVENSTEIN, ERNST GEORG (1834–1913), British geographer, of German origin, was born at Frankfurt-on-Main on Dec. 30 1834, and was educated there. In 1852 he became a pupil of August Petermann, and came to England, where he served in the topographical department of the War Office from 1855 to 1872. As a geographer he was less of a traveller than a research student, and his studies led mainly in the direction of the practice and history of cartography. He compiled many original maps and atlases, bringing a fine critical faculty to bear

upon the data where these were not of the first order of scientific accuracy, as in his series of eastern equatorial Africa, scale 1:1,000,000 (1881-3), and of British East Africa, 1:500,000 (1889). One of his earliest writings was *The Russians on the Amur* (1861), but he was concerned mainly with the history of geography, as exemplified in his *Vasco da Gama's First Voyage* (1898) and *Martin Behaim, his Life and his Globe* (1908), as also in his history of cartography in the *E.B.* (see 17.633). He was an active member of the Royal Geographical Society and of the British Association, over the geographical section of which he presided in 1890, and in which he served as chairman of a committee which made a valuable enquiry into the climatology of Africa. He had also a particular interest in gymnastics, and published a handbook on them in 1867. He died at Hofheim in the Taunus, Germany, March 13 1913.

RAWLINSON, HENRY SEYMOUR RAWLINSON, BARON (1864-), British general, was born Feb. 20 1864, son of Maj.-Gen. Sir H. Rawlinson, Bart. He joined the army in 1884 and a year later became A.D.C. to Sir F. Roberts in India on whose staff he served intermittently for some years. He took part in the Burma operations in 1886-7, and he was on the staff on the Nile in 1897-8, for which he was promoted brevet lieutenant-colonel; he had succeeded to the baronetcy in 1891. He went out to S. Africa on the staff in 1899, served through the defence of Ladysmith, and afterwards joined Lord Roberts and accompanied him to Pretoria and into the eastern Transvaal. Throughout the later stages of the war he commanded a column, and he was rewarded with a brevet colonelcy and the C.B. for his services. Then, after some months at the War Office, he became Commandant of the Staff College, passing on from there in 1906 to the charge of a brigade. He was promoted major-general in 1909 and commanded the 3rd Division from 1910 to May 1914.

He was at first employed at the War Office on the outbreak of the World War, but was in Oct. 1914 selected to command the IV. Army Corps that was being organized. He was in charge of the forces sent to assist Antwerp, and took part in the first battle of Ypres and in the Neuve Chapelle and the Loos offensives, being given the K.C.B. in 1915. He commanded the I. Army temporarily at the end of that year, was promoted lieutenant-general, and on the formation of a IV. Army was placed at its head. He commanded this during the battle of the Somme, achieving important successes, and was promoted general in recognition of his services. At the end of 1917 he was transferred temporarily to the command of the II. Army during Gen. Plumer's absence in Italy, and in Feb. and March 1918 he acted for some weeks as British representative on the Supreme War Council. But he was recalled from this to the field in April to resume command of the IV. Army before Amiens at a critical juncture. On Aug. 8 his troops in conjunction with the French attacked the enemy in this region and they gained a signal victory, which heralded the general advance of the Allies. His army played a prominent part a few weeks later in the storming of the Hindenburg line and in the subsequent victorious advance eastwards. On the final distribution of honours for the war he was raised to the peerage as Baron Rawlinson of Trent, received a grant of £30,000, and was given the G.C.B. In the latter part of 1919 he was sent to N. Russia to conduct the withdrawal of the Allies from Archangel and Murmansk, and on his return he commanded at Aldershot for a year. At the end of 1920 he went out to India as commander-in-chief.

RAYLEIGH, JOHN WILLIAM STRUTT, 3RD BARON (1842-1919), English physicist (see 22.933), died at Witham, Essex, June 30 1919. He was succeeded as 4th baron by his eldest son, ROBERT JOHN STRUTT (b. 1875), already so well-known as a physicist and F.R.S. that he is commonly cited as Strutt when references are made to his scientific papers.

REA, SAMUEL (1855-), American railway official, was born at Hollidaysburg, Pa., Sept. 21 1855. In 1871 he joined the engineering corps of the Pennsylvania railway as chain and rod man, working on several branch lines. From 1875 to 1877 he was engaged, as assistant engineer, in the construction of the chain suspension bridge over the Monongahela river at Pitts-

burgh. He was next appointed assistant engineer for the Pittsburgh and Lake Erie, then under construction. He returned to the Pennsylvania lines in 1879, but ten years later joined the Baltimore and Ohio. For the latter road he was chief engineer for construction of the belt-line tunnel under Baltimore. In 1898 he was appointed an assistant to the president of the Pennsylvania railway and five years later first assistant. In 1899 he was elected fourth vice-president of the Pennsylvania, rising through the various grades to first vice-president in 1911, and when the numerical grades were discarded in 1912 was made vice-president. In 1913 he was elected president. He was also president at times of several other lines, including the Philadelphia, Baltimore and Washington; the West Jersey and Seashore; the Long Island; the Northern Central; and the Pittsburgh, Cincinnati, Chicago and St. Louis. He was in charge of the construction of the Pennsylvania station in New York City (completed in 1911) and the connecting tunnel under the Hudson river, as well as the New York connecting railway and Hell Gate bridge over the East river (opened in 1917). In 1917, after the United States entered the World War, he was appointed by the American Railway Association a member of the special commission on national defense of the Railroads War Board. He was also appointed director of the department of railroads, electric railways, highways, and waterways, of the division of transportation of the Committee of Public Safety of Pennsylvania. In 1917 he presented his private yacht to the U.S. Government for patrol duty in the Atlantic. In 1918, when the railways were taken over by the Government as a war measure, he was replaced as operating head of his road, but remained in charge of its corporate affairs. He was a member of the New York Chamber of Commerce, the American Society of Civil Engineers, the Institution of Civil Engineers of London, and the Society of Naval Architects and Marine Engineers. He was the author of *The Railways Terminating in London* (1888).

READING, RUFUS DANIEL ISAACS, 1ST EARL OF (1860-), British lawyer and statesman, was born in London Oct. 10 1860, of a Jewish family. He was educated at University College school, and later at Brussels and Hanover, and after a brief experience of the London Stock Exchange he was called to the bar in 1887. He speedily earned the reputation of a brilliant lawyer, and in 1898 became a Q.C. In 1904 he entered the House of Commons as Liberal member for Reading, and in 1910 was made solicitor-general and knighted. The same year he became attorney-general, and in June 1912 was given a seat in the Cabinet—the first attorney-general to be so distinguished. In Oct. 1912, Sir Rufus Isaacs's name came under unfavourable discussion during the course of the enquiry into the Marconi contracts, but on the retirement of Lord Alverstone in 1913 he was appointed Lord Chief Justice of England. On the outbreak of the World War his advice on financial questions was of great value to the Government, and he was responsible for some of the most important measures immediately taken by the Treasury in connexion with the situation in the "City." Both at this time and later, his services in the sphere of national finance were, indeed, invaluable. In 1915 he went to the U.S.A. as head of the Anglo-French loan mission, earning golden opinions. He was raised to the peerage as Viscount Reading in 1916, and in 1917 again went as special envoy to America. On his return he was created Earl of Reading, and in 1917, on the retirement of Sir Cecil Spring-Rice, owing to ill-health, went to Washington for a brief period as high commissioner and special ambassador. At the beginning of 1921 he was appointed Viceroy of India in succession to Lord Chelmsford, and resigned the lord chief justiceship. Lord Reading married, in 1887, Alice, daughter of Albert Cohen. His only child, Gerald Rufus Isaacs, Viscount Erleigh (b. 1889), married in 1914 the daughter of Sir Alfred Mond.

RED CROSS WORK.—(1) BRITISH.—The British Red Cross organizations existing before 1905 were, in that year, amalgamated and formed into a new body called the British Red Cross Society. The immediate object of the society was preparation in time of peace for the ultimate work of rendering voluntary

aid to the sick and wounded in war. The War Office, which in the past had been somewhat embarrassed by casual offers of similar help from private individuals, undertook that, in the future, all such offers, other than the supply of certain personnel, should reach them only through the channel of the B.R.C.S., which accordingly began its task under powerful auspices. But it was not at first easy to interest the necessary numbers of people in proceedings depending for fruition on a contingency which most of them believed to be remote. The advance of science, also, together with modern ideas of humanity, had naturally resulted in the creation of an efficient army medical service, possessed of its own military hospitals and nurses, as well as complete equipment for the transport and treatment of wounded men. It was uncertain, therefore, what scope there would be for only partially trained helpers, even if there should be another great war in the future. The formation of the Territorial Force in 1908 provided a solution of the difficulty. Being a volunteer body called into existence for the purpose of home defence, its medical department was not such as would be self-sufficing in a campaign. The War Office accordingly invited the British Red Cross to apply itself to the formation of what are now known as Voluntary Aid Detachments, both of men and women, for service in connexion with the Territorial Force. The members of these detachments were to be prepared by instruction in first aid, sanitation, nursing, ambulance, cooking and other work, and to make provisional arrangements in respect of transport and temporary hospitals for the assistance of regular medical units during military operations in Great Britain. When war broke out in 1914, the B.R.C.S. and the Order of St. John, which was also engaged in organizing V.A.D.'s, had between them 2,374 detachments with a personnel of 70,352. Before the Armistice they numbered 4,083 with a personnel of 125,993. The original idea of the V.A.D. providing supplementary aid to the Territorial medical service was, owing to the exigencies of a European war, thrown into temporary abeyance. Their usefulness, however, was quickly adjusted to the necessities of the hour. They turned to excellent account the arrangements already made in accordance with the War Office scheme, and took a leading part in the transport and reception into auxiliary hospitals of the wounded.

But although the British Red Cross owed to the V.A.D. the advantage of having been able to enroll and educate voluntary workers in time of peace, its main object extended much farther afield. The root idea of the Red Cross is that whatever it can do to save the life or limb of a wounded soldier, or to alleviate his suffering, it is willing to do, without question, whenever and wherever its assistance can be usefully employed; and whatever can be provided to cheer or comfort him, in addition to what the taxpayer supplies, it will provide so long as its funds permit. On the other hand, the medical service of the army exists in order to do all that is reasonably necessary for its patients. That service may fail under stress, as may the army itself; but in principle it does not admit that voluntary aid is indispensable, except in so far as some of it may avoid the necessity for compulsory measures. No doubt, however, arises in connexion with additional comforts. Common sense draws the line between what a Government can be expected to give its wounded men, and what luxury, which must be left to spontaneous generosity on the part of the public acting through the Red Cross. The ostensible appeal of the British Red Cross was therefore for funds to enable the sick and wounded to be given comforts which they would not otherwise receive. But in practice a large part of Red Cross expenditure never strictly meets this description, and much but not all of it relies for defence on the ground that it has been the means of saving life. Thus, the Red Cross war library, which during the war provided over 5,000,000 books for hospitals, etc., and the 2,800 Red Cross work parties and depots, in so far as the articles they produced were not among those in army schedules, may be described as pure Red Cross efforts. But the ambulance launches sent to Mesopotamia for the transport of wounded, though they saved innumerable lives and their cost probably yielded better results, pound for pound,

than any other department of Red Cross work, were nearer the dividing line which separates the field of Red Cross activities from what should be army work. These launches alone carried 414,000 passengers and travelled 683,000 m., while at the various seats of war and in the British Isles Red Cross motor ambulance cars moved 10,000,000 sick and wounded cases. Yet, in fact, the transport of wounded, on which considerably more than £2,000,000 were expended by the Red Cross, was not strictly Red Cross work. It is the business of the army to clear up its own battle-fields at its own cost and take the wounded to hospital. Nevertheless, the enormous number of cases which the Red Cross was allowed to carry remains the best justification for the expenditure incurred until we know what would have happened had voluntary aid not been at hand. It is less easy to account for grants such as those made to the King George Hospital, a military establishment of 1,655 beds set up in the buildings of the Stationery Office, which was equipped by the Red Cross, and towards the expenses of which £154,000 were contributed, two-thirds of that sum being for payment of salaries, wages and ordinary expenses.

On the outbreak of war the B.R.C.S. appealed for funds, as did also the Order of St. John, which had rendered much service in the S. African War. The emergency was altogether exceptional, and the War Office soon broke away from its own regulation as to the sole agency of the B.R.C.S. in respect of voluntary assistance. In the result a joint war committee of the two organizations was formed, subscriptions were pooled, and this committee carried out all Red Cross war work undertaken in Great Britain with some exceptions. Scotland, which elected to proceed separately, raised over £2,000,000, thus providing for a fine independent effort. In addition the principal Dominions Red Cross societies sent commissions to the areas of war where their own contingents were serving, and made generous contributions to the work. Canada, Australia, S. Africa and Egypt were conspicuous examples. India was closely associated with the joint committee in connexion with Mesopotamia and E. Africa, and the American Red Cross gave valuable support. No voluntary collection in Great Britain had ever before reached the amount raised by the Red Cross during the war. Its success was very largely due to the generosity of *The Times*, which opened its columns freely to the advocacy of British Red Cross claims and the acknowledgment of subscriptions. *The Times* fund reached over £16,500,000 and covered many special efforts, such as the annual collections throughout the Empire, known as "Our Day." These produced for the four years in which they were held, over £8,500,000, of which more than five-eighths came from overseas. The farmers sent £1,000,000; the coal-owners and miners nearly £500,000; sales of pictures, jewels, etc., at Christie's amounted to £322,000; church collections to £283,000; and pearls given by ladies from their necklaces were sold for £94,000. Every class of society contributed either in money, work, or kind, and the sums received from individuals varied from 3d. to £25,000.

In addition to the cash which passed through *The Times* fund, gifts of stores to the value of £1,000,000 were made, and a very large unascertained sum was given locally through the auxiliary home hospitals above referred to. These latter, each of which was connected with one of the military centres, were set up in most of the principal towns throughout the country. Private houses, schools and suitable buildings of various kinds were converted into temporary wards, to which, in most instances, the minor cases were sent. They were, as a rule, served by V.A.D. members under a trained nursing staff and local medical men. In some a high degree of efficiency was reached, and to a few wounded were sent direct from the hospital ships. Rent and equipment were provided by subscriptions in the neighbourhood or private munificence, with, when necessary, grants from Red Cross headquarters; and the Government paid a capitation fee in respect of each patient, also affording through the country directors special facilities for rationed food supplies. It is estimated that over 3,200 auxiliary home hospitals were opened during the four years of the war. Their work received warm approval from the Army Council, who issued an inscribed scroll to each building as a permanent memorial of the patriotic purpose to which it had been devoted. That these institutions may claim to have afforded special comfort to wounded soldiers is indicated by the fact that the disciplinary measure most severely felt by refractory patients was their return to the military quarters from whence they came. Apart from the auxiliary home hospitals, a large sum was expended in equipping and maintaining hospitals abroad, special hospitals at home, and convalescent homes. Responsibility for the British Red Cross Society's hospital at Netley and the St. John Ambulance Brigade hospital at Etaples was undertaken by their respective associations. Mention should also be made of the British Red Cross Society's Star and Garter home at Richmond for totally disabled men, an institution intended to provide a harbour for those suffering from incurable spinal paralysis. In all, a sum exceeding

£5,000,000 was spent by the joint committee on hospitals and stores, excluding local expenditure on the auxiliary home hospitals. The stores department covered a great variety of items under general headings, such as textiles, provisions, tobacco, furniture, medical requirements, etc., and involved extensive business arrangements, with warehouses, buyers, and all the machinery of a large commercial establishment. Speed in delivery was a distinguishing feature, and the services of this department were on many occasions invited by the War Office. It was claimed with justice that no reasonable request which it was possible to comply with was ever refused.

A kindred department to the stores was the Central Prisoners of War Committee. The necessity for sending food to prisoners of war had resulted in various efforts which required co-ordination. The Government, as such, being prevented by Germany from supplying food to British prisoners of war, approved the formation of a committee under the Red Cross, which, by resolution of one of its international conferences, was entitled, and was consequently allowed by the enemy, to regard prisoners as coming within its duties. The committee administered a sum of over £4,000,000 and regularly dispatched parcels of bread, other food and clothing to the prison camps. Enquiries for wounded and missing, undertaken by the Red Cross from early in 1915 onwards, were also a much appreciated effort, resulting in over 384,000 reports being obtained at a total cost of less than 3s. 6d. each. Work for interned prisoners in Switzerland and Holland was another undertaking of high character, one of its chief objects being educational and industrial training. Much attention was bestowed by the Red Cross on the after-care of disabled men, both in connexion with accommodation for convalescents, and institutional treatment for patients suffering from neurasthenia, epilepsy, tuberculosis, paralysis and the results of wounds. It is obvious that medical or surgical treatment in such cases may be prolonged and yet not be inconsistent with some form of employment. The Government, realizing this, was prepared to maintain the patients, but difficulties arose on the question of capital outlay: "In any case," says the report of the joint committee, "as far as the Government was concerned, we were faced by delay in circumstances where promptitude was of vital importance to the success of the work. Being ourselves unhampered by restrictions other than the broad objects for which the public had subscribed to the Red Cross, and our funds being immediately available, we were able to obtain the sanction of the Joint Finance Committee for grants which met the necessities of the case. Thus, once again, was demonstrated one of the most valuable uses of such a fund as that administered by the Joint War Committee."

The report from which the foregoing extract is taken deals in detail with Red Cross activities in the various theatres of war, at all of which the joint committee was represented by a commissioner and staff suited to the circumstances. The most extensive work, of course, was that carried out in France and Belgium. There the first commission was sent in Aug. 1914, while the last of many proceeded to Vladivostok a fortnight before the Armistice in 1918. Some idea of the number of people employed by the joint committee will be gained from the fact that the total staff at home and abroad on Oct. 20 1918, was 9,234. Of these 1,353 worked at headquarters in London, 850 of whom were paid and 503 were honorary workers. It is only possible in this article to mention some of the efforts which were specially associated with the Red Cross during the war and have not already been alluded to. The supply of provisional limbs was a useful measure; invalid diet kitchens at Malta, Salonika and Egypt were a new and very successful experiment; and in Italy the ambulance units, among which may be mentioned one devoted to X-ray work, attained some remarkable results. Wherever it was possible to set up recreation rooms or to entertain the wounded, especially at Christmas time, the Red Cross undertook to do so; and at the conclusion of the war, after assisting in repatriation at Berlin and elsewhere, it continued, as it will continue for some years, to look after and help wounded men, particularly while they are waiting for final decisions as to pensions. Although the general direction of Red Cross business was in the hands of men, it is not too much to say that its outstanding feature was women's work. By hospital nursing and organization at home and abroad, motor-driving, rest-station attendance, and general service—including the humblest domestic occupations, to which ladies turned their hands for long periods—British women established a lasting claim to national gratitude; and it may be said that the example they set did more to gain for them their present place in the constitution than several decades of propaganda.

At the end of the war the joint committee was left with a considerable surplus, which approximated roughly to the amount received from the "Our Day" collection taken a few weeks before the Armistice. An Act of Parliament enabled such part of this balance as might not be required for the sick and wounded to be applied to kindred objects. A sum of £1,339,700 was given to civil hospitals and other institutions in England and Wales, and £544,300 to similar purposes in the dominions and colonies.

A heavy distribution of, for the most part, well-earned honours was made to Red Cross workers during and after the war, the chief criticism in connexion with which was that the higher grades allotted to the honorary and paid staff at headquarters in London were out of proportion to those recommended for commissioners and others

who had served for long periods abroad, often under trying conditions and sometimes in no small personal danger. On the whole it may safely be said that the Red Cross war fund was managed on sound business lines which gave general satisfaction to the subscribers, the Government, and the participants in its benefits, and reflected great credit on those who carried out the work.

Stationery Office). (J. D. P.)

(2) **UNITED STATES.**—The "American Association of the Red Cross" was organized in 1881, by the special efforts of Clara Barton (see 3.452) and with the approval of President Garfield and Secretary of State Blaine. Miss Barton was its first president. In 1905 the name was changed to National Red Cross, and the organization was incorporated and nationalized; the President of the United States became its president, and the War Department its auditor. By 1912, state relief boards operating under the National Relief Board of the Red Cross had been organized in practically all of the states in the Union as well as in the Philippine Is. and Porto Rico. In 1913 there were 60 chapters with about 12,000 members. In that year the association provided "disaster relief" in response to 13 calls in the United States and five from abroad. \$3,000,000 were used in relief operations, of which sum one and a third were contributed directly through the Red Cross. In the same year steps were taken to erect a national memorial building in Washington as a tribute to the heroic services, in connexion with the Sanitary Commission and other activities for the benefit of soldiers, rendered by women of the North and South in the Civil War. To an appropriation by Congress of \$400,000, as much more was added by private gifts, and the corner-stone of the building was laid on March 27 1915. The building was occupied as national headquarters early in 1917.

World War Work.—Early in the World War, before America's entry, the Red Cross, with the consent of the Government and in conformity with the treaty of Geneva, offered through the State Department the aid of its trained personnel and contributions of hospital supplies to every country involved in the war. The offer was accepted by all the belligerents with the exception of Belgium, which at first desired only supplies and did not ask for personnel until the spring of 1915. Japan, at first accepting, later declined assistance, as its own Red Cross was able to meet all demands, while Italy, when it entered the conflict, asked only for certain supplies. The Red Cross called the attention of the American people to the contributions made by European Red Cross societies during the Spanish-American War, and the President made a public appeal for funds. As a result, sufficient money was soon at the disposal of the Red Cross to undertake active aid to the various belligerents. Large quantities of hospital supplies and about 200 nurses were sent to Europe and distributed in England, Belgium, France, Germany, Austria, Serbia and Russia. Seventy-one physicians and surgeons were also sent, and a special sanitary commission of 43 doctors and nurses went to Siberia to fight the typhus plague there. The value of the relief supplies sent to Europe by the Red Cross before the United States entered the war exceeded \$1,500,000, of which about \$350,000 worth went to Germany and Austria. In the latter part of 1915, when the sanitary and general medical services of the belligerents had become sufficiently developed to make outside personnel aid unnecessary, the American surgeons and nurses were withdrawn from Europe.

In May 1917, a few weeks after the United States entered the war, President Wilson, as titular head of the American Red Cross, appointed a special Red Cross War Council of seven nationally known men, headed by Henry P. Davison of New York, to direct all the activities of the organization during the war. The first task of this War Council, besides effecting an expansion and elaborate reorganization, was that of obtaining

funds on a large scale to support the extensive work planned. It was decided to appeal at once to the people for a special war fund of \$100,000,000, and President Wilson designated the week of June 18-25 as "Red Cross Week" for the collection of money. Quotas were assigned to each state and city and a vigorous nation-wide campaign was begun. The result was a popular subscription of over \$114,000,000. The second great campaign undertaken by the War Council was a Christmas membership drive during the week of Dec. 17-24 1917. When the United States entered the war the Red Cross membership was about 500,000, comprised in about 500 chapters. By Nov. 1 1917 the membership had increased to 3,000,000, distributed among 3,287 chapters. The first aim of the special membership drive was for 5,000,000 further memberships, but when the campaign was actually launched the goal was set at 10,000,000. At the end of the drive week over 16,000,000 new members had been added to the organization. By the spring of 1918 it was found necessary to launch a new drive for funds, so extensive had been the war undertakings of the Red Cross. Again a nation-wide appeal was made, and during the week May 20-27, approximately \$170,000,000 was subscribed. These two great collections of 1917 and 1918, together with membership dues of about \$17,500,000 and special funds and supplies from various other sources, made up a grand total of a little more than \$400,000,000, of which about two-thirds was available for the needs of the national headquarters and one-third for the special needs of the 3,500 chapters. These special needs were such as purchase of materials to be made into relief articles, local canteen and home service, general operating expenses, etc. The undertakings of the American Red Cross during the war-time and armistice period can be classified under two heads: first, the relations of the Red Cross to the armed forces of the Government both at home and abroad, and second, civilian relief abroad. With regard to the first category a paragraph in a report of the American Red Cross, prepared for the tenth International Red Cross Conference at Geneva on March 30 1921, sets out so admirably the manifold activities carried on that it may well be quoted. It is as follows: "The primary function of the Red Cross in war, of course, is to provide volunteer relief to the sick and wounded, and to serve as a medium of communication between the soldiers, sailors and marines and their families and the American people, but in the late war the American Red Cross activities for the fighting men covered a much wider field. From the time the American soldier entered the service until he had been demobilized, the Red Cross, at the request of the War Department, assisted him in many ways possible only to a large volunteer organization officially recognized. The American Red Cross recruited, organized and equipped hospitals and ambulance units, assisted in the care of the sick and wounded in emergencies, and mobilized nurses for the army and navy. The labour of volunteer Red Cross women provided the men in the service with knitted garments not a part of the army equipment, as well as an unlimited quantity of surgical dressings and supplemental medical supplies. Canteens established at many points in the home country and in the war zone provided the soldier *en route* with food, tobacco and other creature comforts. Home Service helped to maintain *moral* by rendering assistance in many forms to soldiers' and sailors' families. American fighters held prisoners in enemy camps, after being located through the International Red Cross, were supplied by the American Red Cross with food and other comforts. The sick and wounded behind our own lines were cheered and aided in their convalescence, the home-coming and demobilized troops were helped in readjusting themselves to civil life, and, finally, the graves of the fallen were photographed at the request of the War Department for the comfort of the home folks."

The details of the manner and extent of these various activities cannot be described here in detail. Place can be given to only a few special facts. Fifty Red Cross Base Hospital units, each consisting of 22 surgeons and physicians, 65 Red Cross nurses, and 152 Enlisted Reserve Corps men, were sent to England and France and one to Italy for duty with the American Expeditionary Forces. Forty ambulance companies of 124 trained men each were likewise

sent abroad. Over 23,000 trained nurses were mobilized, of whom nearly 20,000 saw active service, one-half of these in Europe. Sanitary service in America was carried on by 29 units of trained personnel assigned to districts in 16 states. A Woman's Volunteer Motor Corps of 11,000 members organized in 300 communities covered over 3,500,000 m. in their activities. Seven hundred canteens staffed by 55,000 women workers were operated in railway stations and camps. Ninety-two convalescent homes were built in the training and embarkation camps. One hundred and thirty canteens were established in France. Also, in France, the Red Cross maintained 24 military hospitals and 12 convalescent hospitals. Thirty-three canteens were established in Italy. Twenty-eight military hospitals and 82 canteens were established just behind the lines in that small part of Belgium never overrun by the Germans. A Home Service with 50,000 workers helped soldiers' families in many ways in America. Finally, 8,000,000 Red Cross women were engaged all through the war in producing comforts and hospital supplies for the American soldiers and sailors. Under the general category of "civilian relief abroad" is included the work done by the American Red Cross, from the time the United States entered the war up to 1921 when this work was still going on, in relieving the civilian populations of the war-ravaged regions of Europe. The distress during the war of the people of the Allied nations, especially in the devastated regions of Belgium, France, Italy, the Balkan States, Poland and Russia, seriously menaced the *moral* of those countries, so that this "civilian relief abroad" by the American Red Cross during the war period was of actual military assistance to the Allies. After the war this assistance, no less necessary, took on a more purely benevolent aspect and was extended in some measure to former enemy countries as well as to the Allies. The largest need and the largest response by the Red Cross was in France. A million and a half refugees from the 10 invaded French departments were scattered throughout other parts of the country. Besides, many Belgian refugees came into France. Disease, especially tuberculosis, threatened to become epidemic. The Red Cross undertook the task, for a time at an expense of \$1,000,000 a month, of housing, clothing, feeding and extending hospital and general medical aid to these civilians. This work was constantly done in association with national and local French organizations. Over 150 such organizations were aided. Sixty-seven hospitals and dispensaries, primarily for refugees, were operated by the Red Cross. Over 30,000 tuberculosis patients were directly reached and helped. A child-welfare campaign was also undertaken, partly of educational character. Special doctors and visiting nurses not only directly helped the children but organized instructional meetings and held special child clinics where modern methods were explained to nearly 300,000 French attendants. Perhaps the second largest item in civilian relief during the war was that of aid to Russia. A special commission was sent to Petrograd by way of Vladivostok, arriving in 1917, while Kerensky was in power, and provided 500,000 cans of condensed milk for children. An ambulance train of 125 cars was also sent to Russia, and \$1,500,000 was devoted to the assistance of Russian soldiers who were returning from the prison camps.

During the war the Red Cross lent assistance to 75 Belgian refugee colonies in free Belgium, France, Switzerland, Holland and England. In Italy 50 kitchens were maintained for needy civilians and direct financial assistance was given to the families of 326,000 Italian soldiers. In Rumania two hospitals and an orphanage were taken over and maintained, and in three districts 40,000 persons were fed daily. Special commissions went to Serbia and Greece and aided materially in caring for refugees and poor families in those countries. In 1918, at the height of the war activities, the American Red Cross had over 20,000,000 adult and 11,000,000 child (junior Red Cross) members comprised in over 3,500 chapters. Eight million of these members were listed as "war workers." The total revenues of the national headquarters and chapters together for the 20 months ending Feb. 28 1919 were \$400,178,000, of which \$272,676,000 was actually expended in war relief work in America and 25 foreign countries during the 20 months' period named, which covered all the time during which the United States was in the war plus the first three and a half months of the Armistice. Of this sum \$169,096,000 was expended by the national headquarters and \$103,580,000 by the various chapters. The former included \$28,978,000 for relief in America; \$57,207,000 in France; \$63,841,000 elsewhere overseas; \$4,660,000 for collections, enrolments, and publications; \$2,727,000 for operation of relief bureaux; \$5,530,000 for operation of bureaux handling relief supplies and transportation in America of these supplies; and \$4,360,000 for operation of administrative bureaux at national headquarters and divisional headquarters. The expenditures of the chapters included \$60,660,000 for materials purchased; \$8,790,000 for home service; \$3,070,000 for military hospitals and ambulances; \$2,320,000 for canteen service; \$1,680,000 for influenza relief; and \$7,490,000 for general operating expenses. The total resources (cash and supplies) of the national headquarters Feb. 28 1919 amounted to \$110,756,000, including unexpended appropriations of \$16,714,000; in addition the chapters had in hand a balance of \$33,460,000. A total of 101,000 tons of relief supplies had been sent overseas; 3,780 French and more than 1,500 Italian hospitals had been aided. The relief articles (surgical dressings, hospital garments and supplies, refugee garments, and various

articles for soldiers and sailors) produced by Red Cross volunteer workers during this time numbered over 370,000,000 of an estimated value of nearly \$100,000,000. Eleven million of these items were knitted articles given to soldiers and sailors in the United States.

Post-war Work.—On March 1 1919, the War Council dissolved and all authority and responsibilities were taken over by the Executive Committee with Dr. Livingston Farrand as chairman. The foreign commissions were gradually closed and withdrawn, although late in 1919 over 1,000 Red Cross workers still remained in Europe. The total membership after the roll-call of Nov. 1919 was about 10,000,000. After the Dec. 1920 roll-call it was about 7,000,000. Relief work was carried on after the war in Albania, Belgium, Bosnia and Herzegovina, Czechoslovakia, France, Great Britain, Greece, Germany, Italy, Montenegro, N. Russia, Palestine, Poland (where more than 100 workers were engaged), Serbia (where 30 doctors, 50 nurses and five dentists worked at various points), S. Russia, Switzerland (caring for American soldier prisoners coming from German prison camps), Siberia (where 600 workers fought against typhus, cholera and other epidemics), and western Russia and the Baltic states. During a part of 1920 operations still continued in most of these countries, but by the end of the year the list had been reduced to Poland, S. Russia, Czechoslovakia, Montenegro, Serbia, the Baltic states, Austria (Vienna), Hungary (Budapest) and Turkey (Constantinople). In Poland 258 hospitals with 26,123 beds were established in 1920. Thirty dispensaries and 207 orphanages were aided, clothing was distributed to over 80,000 children and 2,316 towns with a total population of more than 700,000 were given general relief. In Rumania six hospitals were operated, 322 soup kitchens maintained, and relief supplies provided for 219 schools and 232 orphanages. In western Russia and the Baltic states 300,000 civilian poor, 21,000 refugees and 2,500 war prisoners were helped. In Vienna 98 hospitals were aided. Similar work was done in Budapest. In Siberia the cargoes of 30 American relief ships, and part cargoes of 92 ships from other countries were distributed. Eighteen hospitals were operated and numerous sanitary trains organized and an average of seven articles of clothing was given to each of 387,500 women and 775,000 children. Late in 1920 it was decided to restrict further operations in Europe so far as possible strictly to medical care, and \$5,000,000 was appropriated for this work. Twenty child medical units were put into the field. In America the peace programme of the Red Cross in 1920 contained as its most notable features the further development of its nursing service. Enrolment in this service increased in 1920 from 35,426 to 36,705. The number of Red Cross public health nurses grew from 162 to 908 and the number of women and girls completing the Red Cross course in home hygiene and care of the sick increased during the year from 34,033 to 93,093. There were 57 major disasters in the United States in 1920 which required Red Cross relief. Altogether \$780,000 was expended in this relief.

(V. L. K.)

REDESDALE, ALGERNON BERTRAM FREEMAN-MITFORD, BARON (1837-1916), British politician and writer (see 22.968), in 1906 accompanied Prince Arthur of Connaught on his mission to Japan to invest the Mikado with the Order of the Garter. In 1915 he published his memoirs. He died at Batsford Park, Glos., Aug. 17 1916. His eldest son was killed in action in May 1915, and he was succeeded as second baron by his second son, David Bertram Ogilvy Freeman-Mitford (b. 1877).

REDMOND, JOHN EDWARD (1851-1918), Irish politician (see 22.968*), obtained for the first time a position of real power in Parliament after the first general election of 1910. After he had amalgamated the two Irish Nationalist parties under his own lead in 1900, he had never hitherto been able, owing to the large Unionist majority of 1900, and the independent Liberal majority of 1906, to hold that balance of power in the House of Commons which had proved such a formidable weapon in the hands first of O'Connell and afterwards of Parnell. But the great reduction of the Liberal forces in Jan. 1910 made it impossible that Mr. Asquith's Government should long continue unless it found favour in Mr. Redmond's eyes. The first use which he made of this new authority was to insist that Mr. Lloyd George's famous budget of 1909, on which the dissolution had turned, but which was in itself not very congenial to the Irish party, should be postponed till after the constitutional resolutions directed against the House of Lords—his one object being to remove the veto of the Upper House, which was the main barrier against Home Rule. This order of procedure was also demanded by the Labour party and by the Radicals; and the Government complied. But Redmond did not trust them completely, and pressed for an assurance that the Royal prerogative would be at the Prime Minister's disposal to overbear any rejection by the Lords of the veto resolutions. He regretted King Edward's

death as being a momentary "check to the onward march of the constitutional struggle," and he was impatient at the constitutional conference which was called early in the new reign in order to endeavour—vainly, as the result proved—to discover a solution by consent. He himself occupied the months of its session by a successful expedition to America to secure sympathy and funds. In spite of a harassing movement on his flank by a small party of Independent Nationalists who had Mr. O'Brien and Mr. Healy as their spokesmen, and who accused him of having sold the Irish vote to the Government, he subsequently conducted a strenuous campaign on behalf of the ministerial programme for the second general election of the year. He denounced the House of Lords as the special enemy of Ireland, and said that this was not only a Home Rule election, but the great Home Rule election. When the result of the polling had confirmed him in his tenure of the balance of Parliamentary power, he forwarded the progress of the Parliament bill in 1911 by the steady vote of his party rather than by speech. In the autumn he was regularly consulted on the details of the forthcoming Home Rule bill, and delivered speeches assuring the English that the Home Rule Parliament would be duly subordinate to the Imperial Parliament, and that the Protestants had nothing to fear from Roman Catholic domination, and assuring the Irish that they would find the provisions of the bill satisfactory. When the bill was introduced in April 1912, he welcomed it in the House on behalf of the Nationalists as a great and adequate measure. He disclaimed Separatism, and said that Irish Separatists, once numerous, were now very few, and would disappear when Home Rule was granted. He went over to Ireland and succeeded in almost silencing adverse Nationalist criticism of details, and procured an enthusiastic acceptance of the bill from a Nationalist convention. His speeches during the passage of the bill through Parliament were of a moderate character and accepted the measure as a final settlement; but, while professing goodwill towards Ulster, he resisted any attempt to take her out of the bill as a mutilation of Ireland. In token of the union of feeling between Nationalists and Liberals, he attended the autumn meeting of the National Liberal Federation at Nottingham in Nov. 1912, and spoke for the first time on the same platform as Mr. Asquith, saying that, on every great item of the Liberal programme, the Nationalists were sincerely with them. When, in the next year, these began to talk, in view of the determined attitude of Ulster, of a settlement by consent between parties, he was very slow to agree and was criticised by the Independent Nationalists for his unciliatory attitude. He professed himself ready to discuss further safeguards; but he would not go into a conference at which Home Rule would be "put into the melting pot"; Ireland, he said, was a unit, and the two-nations theory an abomination. In a speech at Newcastle-upon-Tyne on Nov. 14, he denounced the passionate opposition of the Unionists and Ulster as "a gigantic game of bluff and blackmail." He would pay a large price for settlement by consent; but it must be consistent with national self-government for Ireland. He constantly insisted that the bill would, under the Parliament Act, automatically become law in 1914. But, in deference to the general feeling, he said in the debate on the Address in that year that he would consider in the broadest and friendliest spirit any proposals for an agreed settlement that the Government might make, though he protested against the idea of an Amending bill. When Mr. Asquith proposed the scheme of provisional exclusion, by county option, for six years, he treated this as the extreme limit of concession, and consequently this was the proposal which the Government embodied in their Amending bill. He absolutely refused to consider the total exclusion of Ulster. He had difficulties with the extremists in Ireland that spring and summer. The enrolment of the Ulster Volunteers had suggested the idea of similar formations in the other three provinces to defend the Nationalist idea; and under the fostering of leaders like Casement and of the rising Sinn Féin organization, these forces had reached large numbers—over 100,000 by the spring of 1914. Their growth had been discouraged by Mr. Redmond and his colleagues;

* These figures indicate the volume and page number of the previous article.

But he felt it necessary now to obtain control, and, after a somewhat sharp struggle with the extremists, succeeded in doing so in June. At the end of July he took part, in spite of Nationalist criticism, in the abortive Buckingham Palace Conference. Then came the World War, and in the debate succeeding Sir E. Grey's famous declaration on bank holiday, Aug. 3, Redmond created a profound sensation by a speech in which he declared that the events of recent years had completely altered the Nationalist feeling towards Great Britain. The Government, he said, might withdraw its troops from Ireland, whose coasts would be defended by her own sons, Nationalist Volunteers joining with Ulster Volunteers in the task. This generous attitude was met by the decision of the Government to pass the Home Rule bill into law, suspending its operation till after the war. Redmond took an active part in promoting recruiting in Ireland. He stood on the platform in Dublin Mansion House on Sept. 25 by the side of the Prime Minister and the Lord Lieutenant, and said that Ireland would feel bound in honour to take her place beside the other autonomous portions of the King's dominions. "You have kept faith with Ireland," he said; "Ireland will keep faith with you." Unfortunately, owing partly to the anti-recruiting agitation promoted by Sinn Féin and other extremists, and partly to red tape at the War Office, his efforts were only moderately successful. But he constantly opposed the application of conscription in any shape to Ireland, and in consequence neither of the military service bills of the spring of 1916 applied to that country. He had refused Mr. Asquith's request for his help in office in the Coalition Government of June 1915; and the fact that he stood out, while Sir E. Carson was included, no doubt intensified the smouldering dissatisfaction in southern Ireland, which broke into a blaze in the Dublin Rebellion of Easter 1916. This was a stunning blow to Redmond, who had not realized the growing strength and virulence of the Sinn Féin movement. He expressed in the House of Commons his detestation of the crime, and lent his assistance to the attempt that was made by the Government in the summer through Mr. Lloyd George to arrange an agreed settlement of the whole Irish question. At first it looked as if the negotiations would be successful, on the basis of bringing the Home Rule Act into immediate operation, while excluding the six Ulster counties by an Amending bill which should cover all the period of the war, and a short interval after it. The consent was obtained of all Irish parties, except the southern Unionists; but certain modifications which the Unionists in the Cabinet demanded were treated by the Nationalists as amounting to a breach of faith; and Redmond announced his intention of criticising ministers for their procrastination not only with regard to Ireland but also with regard to the whole conduct of the war. The negotiations having failed, and the Government having restored the ordinary civil administration of Ireland, with Mr. Duke, K.C., a Unionist, as Chief Secretary, Redmond treated this as a fresh outrage on Ireland; and on Oct. 18 he moved a resolution charging ministers with maintaining a system of government in Ireland inconsistent with the principles for which the Allies were fighting in Europe. The result, he said, was that Irish regiments could not be kept up to their full strength, and that his efforts to aid recruiting had been nullified. The motion was, of course, rejected by a large majority. He criticised Mr. Lloyd George's administration in March 1917 on similar lines, and threatened a return by his party to the old obstructionist opposition. In May, however, the Prime Minister suggested among other alternatives that an Irish convention should be assembled for the purpose of producing a scheme of Irish self-government. To this Redmond agreed; and in the convention he played a prominent and conciliatory part, making in particular a favourable impression on the southern Unionists. During its sittings, however, his health failed. He died of heart failure in London on March 6 1918.

In private life, John Redmond was much liked among his friends, but he never went much into society. He was happily married to an Australian lady, Miss Dalton, by whom he had a son and two daughters.

His younger brother, WILLIAM HOEY KEARNEY REDMOND (1861-1917), intended, as a young man, to adopt the army as his profession, and in 1881 he was a lieutenant in the co. Wexford militia battalion of the Royal Irish Regiment. But he resigned his commission to take part in the Land League movement, was imprisoned as a "suspect" in Kilmainham, and went to Australia with his brother to raise funds for the Nationalist agitation. He was returned for Wexford borough in 1883, and sat in Parliament, though for different constituencies, from that time till his death. He was of an ardent and ebullient temper, which resulted in his spending three months in Wexford gaol in 1888 for inciting to resistance to the sheriff, on the occasion of an eviction, and in many agitated scenes at different times in the House of Commons, where, however, he was personally very popular. Like his brother, in the Nationalist split he adhered to Parnell, and also like his brother, on the outbreak of the World War he instantly recognized the duty of Ireland to fling herself into it on the side of the Allies. Though 53 years old, he joined at once the Irish Division, receiving a commission in the Royal Irish Regiment. He was promoted major for services at the front and mentioned in despatches. In his intervals of service he made two thrilling speeches in the House of Commons—one in Dec. 1916, in which he advocated a new Ireland built up out of the war, and declared that Nationalists and Ulstermen came together in the trenches and were friends, and that if they were brought together on the floor of an assembly in Ireland they would be friends too; the other in March 1917, when he besought the House to let the dead past bury its dead, and to make a new start between England and Ireland. He died of wounds in France on June 7 1917.

REDWOOD, SIR BOVERTON, BART. (1846-1919), British chemist, was born in London April 26 1846. He was educated at University College school, London, and by the Pharmaceutical Society, specialized in the study of petroleum and became in 1869 secretary to the Petroleum Association. In this connexion he gave evidence before a select committee of the House of Lords, and his investigations throughout Europe and America qualified him to be the adviser of the Government as to the best use of petrol and oil fuel both before and during the World War. He founded the Institution of Petroleum Technologists and became its first president. He was knighted in 1905 and created a baronet in 1911. He died in London June 4 1919.

REHAN, ADA (1860-1916), American actress (see 23.48), died in New York City Jan. 8 1916.

REID, SIR GEORGE (1841-1913), British painter (see 23.50), died at Oakhill, Som., Feb. 9 1913.

REID, SIR GEORGE HOUSTON (1845-1918), Australian statesman, was born at Johnstone, Renfrewshire, Feb. 25 1845. His father, a Presbyterian minister, emigrated to Australia seven years later, and the boy was therefore Australian by education though not by birth. At the age of 13 he became a junior clerk in a business house in Sydney, but later entered the N.S.W. civil service and began to read for the bar, being finally called in 1879. Politics attracted him more than law, and in 1880 he was elected member for E. Sydney, together with Sir Henry Parkes but above him in the poll. He stood as a free trader, a policy to which he adhered throughout his political career, and with one short break (1884-5) he represented E. Sydney in the N.S.W. Legislature until 1901 when he was elected its representative in the Federal Parliament. He first held office in N.S.W. for a brief period in 1883-4 as Minister of Public Instruction. In 1894 he became its Premier and during his term of office (1894-9) introduced reforms into the civil service and represented the Colony at Queen Victoria's Diamond Jubilee. He did much to promote Federation and from 1901-9 led the free-trade party in the Federal Parliament, becoming Premier for a short period (1904-5) but being for the most part leader of the Opposition. When the Act to constitute an Australian High Commissionership was passed in 1909 Sir George Reid became the first High Commissioner and was created K.C.M.G. He represented his country in London in genial fashion until 1916, and at the end of his term of office

stood for the British House of Commons and was elected for the St. George's Hanover Square division of London Jan. 1916. He was created G.C.M.G. in 1911 and G.C.B. in 1916. He published *My Reminiscences* (1917), as well as *Five Free Trade Essays* (1875), and other economic papers. He died suddenly in London, Sept. 12 1918.

REID, WHITELAW (1837-1912), American journalist and diplomatist (see 23.52), died in London Dec. 15 1912. His last public address was delivered before the students of the University College of Wales, Aberystwyth, on "Thomas Jefferson." In 1912 appeared *The Scot in America and the Ulster Scot* and posthumously, in 1913, *American and English Studies*.

See Royal Cortissoz, *The Life of Whitelaw Reid* (1921).

REINACH, JOSEPH (1856-1921), French author and politician (see 23.55), was not re-elected to the Chamber of Deputies in 1914. During the World War his series of articles, "Les Commentaires de Polybe," in the *Figaro*, were remarkable for their clear vision. He died April 18 1921.

RÉJANE, GABRIELLE [CHARLOTTE RÉJU] (1857-1920), French actress (see 23.58), died in Paris June 14 1920. During the World War she visited England and appeared at the Court theatre, London, in a patriotic play, *Alsace*, and at the Coliseum in *The Bel*, when she played the part of a Frenchwoman visiting the English battle-zone. She was made Chevalier of the Legion of Honour for her war services.

RELATIVITY.—The progress of physical science during the decade 1910-20 was specially remarkable for the definite emergence into general public discussion of the principle of Relativity, as expounded by Prof. Albert Einstein, professor of Physics in the Kaiser Wilhelm Institut, Berlin. Its meaning and its history as part of present-day physical theory are discussed below.

Introduction.—The primary aim of the investigator in pure science is the discovery of natural laws. As a secondary and hardly less important aim, he tries to invent a mechanism which shall account for the laws already known. The secondary aim is forced upon him partly by the constitution of the human mind; our intellects, unsatisfied with a mere accumulation of facts, impel us ever to search for the causes underlying the facts: *Vere scire est per causas scire*. But to the working scientist the discovery of a mechanism has an additional and more practical value. When he has found a mechanism which will account for certain laws, he can proceed to examine the complete set of laws which the mechanism demands. If his mechanism corresponds with sufficient closeness to reality he may in this way be led to the discovery of new natural laws. On the other hand, the new laws deduced from the supposed mechanism may be false. If the falsity of the new laws is not at once revealed science may for a time be led into wrong paths. When more accurate experimenting or observation discloses that the laws are not true, a recasting of ideas becomes necessary, and the branch of science concerned may experience a time of revolution followed by a period of rapid growth.

An obvious illustration of these general statements is provided by the history of astronomy. The laws of the motions of the planets, as observed from the earth, were tolerably well known to the Greeks. They had also evolved an explanatory mechanism, starting from the metaphysical premise that the paths of the planets must necessarily be circles. The earth was the centre of the universe and round this revolved spheres to which the planets were attached. To explain the retrograde motion of the outer planets, these were supposed attached to secondary spheres revolving about points on the primary spheres which in turn revolved about the earth. This mechanism of cycles and epicycles held the field as an explanation of planetary motion for eighteen centuries. Finally the observations of Tycho Brahe provided a test which revealed the falsity of the whole structure. The position of Mars was found to differ from that required by the mechanism of epicycles by an amount as great as eight minutes of arc. "Out of these eight minutes," said Kepler, "we will construct a new theory that will explain the motions of all the planets."

The history of the succeeding century of astronomy need not be recapitulated here (see 2.811). The earth yielded its place as the centre of the universe, and the structure of cycles and epicycles crumbled away. The laws of planetary motion were determined with a precision which for the time appeared to be final. The mechanism underlying these laws was supposed to be a "force" of gravitation. This force was supposed to act between every pair of particles in the universe, its intensity varying directly as the product of the masses of the particles and inversely as the square of the distance separating them—the famous law of Newton.

In science, history repeats itself. Recent years have provided a further instance of the general processes we have been considering. Under the Newtonian mechanism every planet would describe a perfect ellipse about the sun as focus, and these elliptic orbits would repeat themselves indefinitely except in so far as they were disturbed by the gravitational forces arising from the other planets. But, after allowing for these disturbing influences, Leverrier found that the orbit of the planet Mercury was rotating in its own plane at the rate of 43 seconds a century. Various attempts have been made to reconcile this observed motion with the Newtonian mechanism. The gravitational forces arising from the known planets were demonstrably unable to produce the motion in question, but it was possible that Mercury's orbit was being disturbed by matter so far unknown to us. Investigations were made as to the disturbance to be expected from various hypothetical gravitating masses—a planet, or a ring of planets, between Mercury and the sun, a ring of planets outside the orbit of Mercury, a belt of matter extended in a flattened disc in a plane through the sun's centre, an oblateness, greater than that suggested by the shape of the sun's surface, in the arrangement of the internal layers of the sun's mass. In every case the mass required to produce the observed disturbance in the motion of Mercury would have also produced disturbances not observed in the motions of the other planets. The solution of the problem came only with the theory of relativity. Just as Tycho's eight minutes of arc, in the hands of Kepler and Newton, revolutionized mediæval conceptions of the mechanism of the universe, so Leverrier's 43 seconds of arc, in the hands of Einstein, has revolutionized our 19th-century conceptions, not only of purely astronomical mechanism, but also of the nature of time and space and of the fundamental ideas of science. The history of this revolution is in effect the history of the theory of relativity. It falls naturally into two chapters, the first narrating the building of an earlier physical theory of relativity, and the second dealing with its extension to gravitation.

The Physical Theory of Relativity.—The earliest successful attempt to formulate the laws governing the general motion of matter is found in Newton's laws. The first law states that—

"Every body perseveres in its state of rest or of uniform motion in a right line unless it is compelled to change that state by forces impressed thereon."

In this law no distinction is made between rest and uniform motion in a straight line, and the same is true of the remaining laws. Hence follows the remarkable property to which Newton draws explicit attention in his fifth corollary to the laws of motion:—

"The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forward, in a right line without any circular motion."

As a concrete application of this principle, Newton instances "the experiment of a ship, where all motions happen after the same manner whether the ship is at rest or is carried uniformly forward in a right line." Just as a passenger on a ship in a still sea could not determine, from the behaviour of bodies inside the ship, whether the ship was at rest or moving uniformly forward, so we cannot determine from the behaviour of bodies on our earth whether the earth is at rest or not. We believe the earth to be moving round the sun with a speed of about 30 km. a second, so that there can be no question of the earth being permanently at rest, but we are unable to determine whether

it is at rest at any specified point of its orbit, or, in the probable event of its not being at rest, what its absolute velocity may be. There is no more reason for thinking the sun, than the earth, to be at rest. Newton wrote as follows:—

"It is possible that in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, but impossible to know, from the positions of bodies to one another in our regions, whether any of these do keep the same position to that remote body. It follows that absolute rest cannot be determined from the position of bodies in our regions."

The above quotations are all from the first book of the *Principia Mathematica*. Previous to them all Newton writes: "I have no regard in this place to a medium, if any such there is, that freely pervades the interstices between the parts of bodies." The two centuries which elapsed after the publication of the *Principia* witnessed a steady growth of the belief in the reality of such an all-pervading medium. It was called the aether, and by the end of these two centuries (1887) it was almost universally believed that light and all electromagnetic phenomena were evidence of actions taking place in this aether. Light from the most distant stars was supposed to be transmitted to us in the form of wave motions in the aether, and we could see the stars only because the sea of aether between us and these stars was unbroken. It had been proved that if this sea of aether existed it must be at rest, for the alternative hypothesis that the aether was dragged about by ponderable bodies in their motions had been shown to be incompatible with the observed phenomenon of astronomical aberration and other facts of nature (see 1.202). On this view it was no longer necessary to go to Newton's "remote regions of the fixed stars, or perhaps far beyond them," to find absolute rest. A standard of absolute rest was provided by the aether which filled our laboratories and pervaded all bodies. Owing to our motion it would appear to be rushing past us, although without encountering any hindrance—"like the wind through a grove of trees," to borrow the simile of Thomas Young. The determination of the absolute velocity of the earth was reduced to the problem of measuring the velocity of an aether current flowing past us and through us.

In this same year (1887) the first experimental determination of this velocity was attempted by the Chicago physicist A. A. Michelson. The velocity of light was known to be, in round numbers, 300,000 km. a second, a velocity which was believed to represent the rate of progress of wave motion through the aether. If the earth were moving through the aether with a velocity of 1,000 km. a second, the velocity of light relative to a terrestrial observer ought to be only 299,000 km. a second when the light was sent in exactly the direction of the earth's motion through the aether, but would be 301,000 km. a second if the light was sent in the opposite direction. In more general terms, if the earth were moving through the aether, the velocity of light, as measured by a terrestrial observer, would depend on the direction of the light, and the extent of this dependence would give a measure of the earth's velocity. The velocity of light along a single straight course does not permit of direct experimental determination, but the same property of dependence on direction ought to be true, although to a less extent, of the average to-and-fro velocity of a beam of light sent along any path and then reflected back along the same path.

It was through this property that Michelson attempted to measure the earth's velocity through the aether.

The apparatus was simple in principle. A circular table ABCD was arranged so as to be capable of slow rotation about its centre O. Light sent along CO was divided up at O into two beams which were made to travel along perpendicular radii OA, OB. The arms OA, OB were made as equal as possible and mirrors were placed at A and B to reflect the beams of light back to O. An extremely sensitive optical method made it possible to detect even a very slight difference in the times of the total paths of the two beams from O back to O. There would in any case be a difference owing to the necessarily imperfect equalization of the lengths of the arms OA, OB, but if the earth is moving through the aether in some direction OP, and if the table is made to rotate slowly about O, then this difference ought itself to vary on account of the earth's motion through the aether. Michelson, and afterwards Michelson and Morley in collaboration, attempted to estimate the amount of this variation.

No variation whatsoever could be detected, although their final apparatus was so sensitive that the variation produced by a velocity through the aether of even 1 km. a second ought to have shown itself quite clearly.

Thus to the question "What is our velocity through the aether?" Nature appeared to give the answer "None." It was never suggested that this answer should be accepted as final; it would have brought us back to a geocentric universe. Clearly either the question had been wrongly framed or the answer wrongly interpreted. It was pointed out in 1893 by Fitzgerald, and again, independently, in 1895, by Lorentz, that the *null* result of the Michelson-Morley experiment could be explained if it could be supposed that motion through the aether altered the linear dimensions of bodies.

FIG. 1.

FIG. 2.

To be explicit, it was found that the experiment would invariably and of necessity give a *null* result if it was supposed that every body moving through the aether with a velocity u was contracted

in the direction of its motion in the ratio $\sqrt{1 - \frac{u^2}{c^2}}$, c being the

velocity of light. The supposition that such a contraction occurred was not only permissible—it was almost demanded by electrical theory. For Lorentz had already shown that if matter were a purely electrical structure, the constituent parts would of necessity readjust their relative positions when set in motion through the aether and the final position of equilibrium would be one showing precisely the contraction just mentioned.

On this view, there was no *prima-facie* necessity to abandon the attempt to measure the earth's velocity through the aether. The answer to the problem had merely been pushed one stage farther back, and it now became necessary only to measure the shrinkage of matter produced by motion. It was obvious from the first that no direct material measurement could disclose the amount of this shrinkage, since any measuring rod would shrink in exactly the same ratio as the length to be measured; but optical and electrical methods appeared to be available. Experiments to this end were devised and performed by Rayleigh, Brace, Trouton and Noble, Trouton and Rankine and others. In every case a *null* result was obtained. It appeared then that if the earth moved through the aether this motion was concealed by a universal shrinkage of matter, and this shrinkage was in turn concealed by some other agency or agencies whose wit, so far, appeared to be greater than that of man.

At this time the word "conspiracy" found its way into the technical language of science. There was supposed to be a conspiracy on the part of the various agencies of nature to prevent man from measuring his velocity of motion in space. If this motion produced a direct effect x on any phenomenon, the other agencies of nature seemed to be in league to produce a countervailing effect $-x$. A long train of experiments had not revealed, as was intended, our velocity through the aether; they had merely created a conviction that it was beyond the power of man to measure this velocity. The conspiracy, if such there was, appeared to have been perfectly organized.

A perfectly organized conspiracy of this kind differs only in name from a law of nature. To the inventor who tries to devise a perpetual-motion machine it may well appear that the forces of nature have joined in a conspiracy to prevent his machine from working, but wider knowledge shows that he is in conflict not with a conspiracy, but with a law of nature—the conservation of energy. In 1905 Einstein, crystallizing an idea which must

have been vaguely present in many minds, propounded the hypothesis that the apparent conspiracy might be in effect a law of nature. He suggested, tentatively, that there might be a true law to the effect that "it is of necessity impossible to determine absolute motion by any experiment whatever." This hypothetical law may again be put in the equivalent form: "The phenomena of nature will be the same to two observers who move with any uniform velocity whatever relative to one another." This may be called the hypothesis of relativity.

The hypothesis in itself was not of a sensational character. Indeed, from the quotations which have already been given from Newton's works, it appears probable that Newton himself would have accepted the hypothesis without hesitation: he might even have regarded it as superfluous. The true significance of the hypothesis can only be understood by a reference to the scientific history of the two centuries which had elapsed since Newton. The Newtonian view that absolute rest was to be found only "in the remote regions of the fixed stars, or perhaps far beyond them," had given place to a belief that absolute rest was to be found all around us in an aether which permeated all bodies. What was striking about the hypothesis was its implication—either that we could not measure the velocity relative to ourselves of a medium which surrounded us on all sides, or else that no such medium existed.

The hypothesis demanded detailed and exhaustive examination. It was for the mathematician to test whether the hypothesis was in opposition to known and established laws of physics, and to this task Einstein, Lorentz and others set themselves. If a single firmly established law proved to be in opposition to the hypothesis, then of course the hypothesis would require to be abandoned. It was unlikely that such an event would occur among the well-established laws, for if it did, the phenomena governed by that law would enable direct measurement to be made of the earth's velocity through the aether, a measurement which had so far eluded all attempts of experimenters. It was among the more obscure and less well-established laws, if anywhere, that discrepancies were to be looked for.

It is impossible here to give a complete account of the many tests to which the relativity hypothesis has been subjected. The result of all can be summed up in one concise and quite general statement:—Wherever the hypothesis of relativity has appeared to be in conflict with known or suspected natural laws, further experiment, where possible, has, without a single exception, shown the laws to be erroneous, and has moreover shown the alternative laws suggested by the hypothesis of relativity to be accurate. It is only in somewhat exceptional cases that the hypothesis of relativity of itself suffices to determine fully the form of a natural law; these cases constitute the most striking triumphs of the theory. As instances may be mentioned the determination of the law connecting the mass of an electron with its velocity; of the law expressing the velocity of light through a transparent medium in motion (Fizeau's water-tube experiment); and of the formulae for the magnetic forces on moving dielectric media (experiments of Eichenwald and H. A. Wilson).¹

Before passing on from the general statement which has been made, particular mention must be made of one special case. A natural law which was at an early stage seen to be in conflict with the hypothesis of relativity was Newton's famous law of gravitation—namely, that every particle of matter attracts every other particle with a force proportional to the product of the two masses, and to the inverse square of their distance apart. Either, then, Newton's great law had to be abandoned, or else the hypothesis of relativity had to be discarded, in which case it would immediately become possible, in theory at least, to determine the earth's velocity through space by gravitational means. It is the choice between these two alternatives that has led to the most surprising developments of the theory of relativity; and to these we shall return later.

¹ For references to the original papers dealing with these and other tests of the hypothesis of relativity see Cunningham, *The Principles of Relativity*, or J. H. Jeans, *Mathematical Theory of Electricity and Magnetism* (4th ed.).

Space and Time.—The hypothesis of relativity, as has already been explained, postulates that the phenomena of nature will be the same to any two observers who move relative to one another with any uniform velocity whatever. The hypothesis has been so amply tested as regards all optical and electromagnetic phenomena that no doubt is felt, or can rationally be felt, as to its truth with respect to these phenomena. The hypothesis can be examined and developed in two opposite directions. We may, on the one hand, proceed from the general hypothesis to the detailed laws implied in it; this has already been done, with completely satisfactory results as regards confirmation of the hypothesis. Or we may regard the hypothesis of relativity as being itself a detailed law and attempt to generalize upward to something still wider. It is this possibility which must for the moment claim our attention.

In 1905 Einstein examined in full the consequences of the hypothesis that one simple optical phenomenon—namely, the transmission of a ray of light in free space—was, in accordance with the hypothesis of relativity, independent of the velocity of the observer. If an aether existed, and provided a fixed framework of reference, then light set free at any instant would obviously travel with a velocity which would appear to an observer at rest in this aether to be the same in all directions, and the wave front at any instant would be a sphere having the observer as centre. On the hypothesis of relativity the phenomenon of light transmission must remain unaffected by the motion of the observer, so that the light must appear to a moving observer also, to travel with a uniform velocity in all directions, and thus to the moving observer also the wave front must appear to be a sphere of which he will be the centre. It is, however, quite obvious that the same spherical wave front cannot appear to each of two observers who have moved some distance apart to be centred round himself, unless the use either of the common conceptions of science or of the ordinary words of language is greatly changed. In fig. 2 it is not possible in ordinary language that both O and P should at the same instant be at the centre of the sphere A B C. The change to which Einstein was forced is one which has an intimate bearing upon our fundamental conceptions of the nature of space and time; this change it will be necessary to explain in some detail.

Suppose that two observatories, say Greenwich and Paris, wish to synchronize their clocks, with a view to, let us say, an exact determination of their longitude difference. Paris will send out a wireless signal at exact midnight as shown by the Paris clock, and Greenwich will note the time shown by the Greenwich clock at the instant of receipt of the signal. Greenwich will not, however, adjust their clock so as to show exact midnight when the signal is received; a correction of about .001 second must be made to allow for the time occupied by the signal in traversing the distance from Paris to Greenwich. To turn to mathematical symbols, if t_0 is the time at which a signal is sent out from one station, the time of receipt at a second station is taken to be $t_0 + \frac{x}{c}$, where x is their distance apart, and

c is the velocity of light. This represents the ordinary practice of astronomers, but it is clear that if the earth is travelling through a fixed aether with a velocity u in the direction of the line joining the two observatories, the velocity of transmission of the signal relative to the two observatories will not be c but $c+u$, and the time of receipt at the second station will be $t_0 + \frac{x}{c+u}$. Thus it

appears that it is impossible to synchronize two clocks unless we know the value of u , and that the ordinary practice of astronomers will not, as they expect, synchronize their clocks, but set them at an interval apart equal to

$$x \left(\frac{1}{c} - \frac{1}{c+u} \right)$$

which may, to an approximation, be put equal to $\frac{ux}{c^2}$.

According to the hypothesis of relativity, it is impossible ever to determine the value of u , and so is impossible ever truly

to synchronize two clocks. Moreover, according to this hypothesis, the phenomena of nature go on just the same whatever the value of u , so that the want of synchrony cannot in any way show itself—in fact, if it did, it would immediately become possible to measure the effect and so arrange for true synchrony.

As the earth moves in its orbit, the value of u changes, so that its value in the spring, for instance, will be different from its value in the autumn. One pair of astronomers may attempt to synchronize a pair of clocks in the spring, but their synchronization will appear faulty to a second pair who repeat the determination in the autumn. There will, so to speak, be one synchrony for the spring and another for the autumn, and neither pair of astronomers will be able to claim that their results are more accurate than those of their colleagues. More generally we may say that different conceptions of synchrony will correspond to different velocities of translation.

These elementary considerations bring us to the heart of the problem which we illustrated diagrammatically in fig. 2. The observer at O in the diagram will have one conception of simultaneity, while the second observer who moves from O to P will, on account of his different velocity, have a different conception of simultaneity. The instants at which the wave front of the light signal from O reaches the points A, B, C in the diagram will be deemed to be simultaneous by the observer who remains at O, but the observer who moves from O to P will quite unconsciously have different ideas as to simultaneity. At instants which he regards as simultaneous the wave front will have some form other than that of the sphere ABC surrounding O. If the hypothesis of relativity is to be true in its application to the transmission of light signals, this wave front must be a sphere having P as its centre.

Einstein examined mathematically the conditions that this should be possible. Unfortunately a precise statement of his conclusions can only be given in mathematical language.

The observer who is supposed to remain at O in fig. 2 may be supposed to make exact observations and to record these observations in mathematical terms. To fix the positions of points in space he will map out a "frame of reference" consisting of three orthogonal axes, and use Cartesian coördinates x, y, z , to specify the projections along these axes of the radius from the origin to any given point. He will also use a time coördinate t which may be supposed to specify the time which has elapsed since a given instant, as measured by a clock in his possession. Any observations he may make on the transmission of light signals can be recorded in the form of equations between the four coördinates x, y, z, t . For instance, the circumstance that light travels from the origin with the same velocity c in all directions will be expressed by the equation (of the wave front):—

$$x^2 + y^2 + z^2 - c^2 t^2 = 0. \quad (1)$$

The second observer who moves from O to P will also construct a frame of reference, and we can simplify the problem by supposing that his axes are parallel to those already selected by the first observer. His coördinates, to distinguish them from those used by the first observer, may be denoted by the accented letters x', y', z', t' . If his observations also are to show light always to travel with the same velocity c in all directions, the equation of the wave front, as observed by him, must be:—

$$x'^2 + y'^2 + z'^2 - c^2 t'^2 = 0. \quad (2)$$

A 19th-century mathematician would have insisted that x, y, z, t must be connected with x', y', z', t' by the simple relations:—

$$\left. \begin{aligned} x' &= x - ut \\ y' &= y \\ z' &= z \\ t' &= t \end{aligned} \right\} \quad (A)$$

but it is obvious that if these relations hold, then equation (1) cannot transform into equation (2). Einstein finds that equation (1) will transform into equation (2) provided the coördinates x, y, z, t of the first observer are connected with the coördinates x', y', z', t' of the second observer by the equations:—

$$\left. \begin{aligned} x' &= \beta (x - ut) \\ y' &= y \\ z' &= z \\ t' &= \beta \left(t - \frac{ux}{c^2} \right) \end{aligned} \right\} \quad (B)$$

where β stands for $\left(1 - \frac{u^2}{c^2} \right)^{-\frac{1}{2}}$.

To form some idea of the physical meaning of these equations, it will be advantageous to consider the simple case in which the first observer is at rest in the aether while the second moves through the aether with velocity u . The points of difference between equations (B) and (A) then admit of simple explanation. The factor β in the first of equations (B) is simply, according to the suggestion of Fitzgerald and Lorentz already mentioned, the factor according to which all lengths parallel to the axis of x must be adjusted on account of motion through the aether with velocity u . The moving observer must correct his lengths by this factor, and he must correct his times by the same factor in order that the velocity of propagation of light along the axis of x may still have the same velocity c ; this explains the presence of the multiplier β in the last of equations (B). The one remaining difference between the two sets of equations, namely the replacement of t in (A) by $t - \frac{ux}{c^2}$ in (B), represents exactly the

want of synchrony which, as we have already seen, is to be expected in the observations of two observers whose velocity differs by a velocity u .

Although the equations admit of simple illustration by considering the case in which one observer is at rest in a supposed aether, it will be understood that the equations are more general than the illustration. They are in no way concerned with the possibility of an observer being at rest in an aether, or indeed with the existence of an aether at all. Their general interpretation is this: If one observer O, having any motion whatever, finds, as a matter of observation, that light for him travels uniformly in all directions with a constant velocity c , then a second observer P, moving relative to O with a constant velocity u along the axis of x , will find, as a matter of observation, that light, for him also, travels uniformly in all directions with the same constant velocity c , provided he uses, for his observations, coördinates which are connected with the coördinates of O by equations (B).

This is the meaning that was attached to the equations by Einstein in 1905, but the equations had been familiar to mathematicians before this date. They had in fact been discovered by Lorentz in 1895 as expressing the condition that all electromagnetic phenomena, including of course the propagation of light, should be the same for an observer moving through the aether with velocity u as for an observer at rest in the aether. For this reason the transformation of coördinates specified by these equations is universally spoken of as a "Lorentz transformation." What Einstein introduced in 1905 was not a new system of equations but a new interpretation of old equations. The two observers who used the coördinates x, y, z, t and x', y', z', t' had been regarded by Lorentz as being one at rest in an aether and one in motion with a velocity u ; for Einstein they were observers moving with any velocities whatever subject to their relative velocity being u . Lorentz had regarded t as the true time and t' as an artificial time. If the observer could be persuaded to measure time in this artificial way, setting his clocks wrong to begin with and then making them gain or lose permanently, the effect of his supposed artificiality would just counterbalance the effects of his motion through the aether. With Einstein came the conception that both times, t and t' , had precisely equal rights to be regarded as the true time. The measure t' is precisely that which would be adopted naturally by any set of observers, or race of men, who disregarded their steady motion through space; their adoption of it would be above criticism if, as Einstein suggested, their motion through space had no influence on material phenomena, and it represents, as we have seen, the usual practice of astronomers in comparing time at different places. From this point of view,

have been vaguely present in many minds, propounded the hypothesis that the apparent conspiracy might be in effect a law of nature. He suggested, tentatively, that there might be a true law to the effect that "it is of necessity impossible to determine absolute motion by any experiment whatever." This hypothetical law may again be put in the equivalent form: "The phenomena of nature will be the same to two observers who move with any uniform velocity whatever relative to one another." This may be called the hypothesis of relativity.

The hypothesis in itself was not of a sensational character. Indeed, from the quotations which have already been given from Newton's works, it appears probable that Newton himself would have accepted the hypothesis without hesitation: he might even have regarded it as superfluous. The true significance of the hypothesis can only be understood by a reference to the scientific history of the two centuries which had elapsed since Newton. The Newtonian view that absolute rest was to be found only "in the remote regions of the fixed stars, or perhaps far beyond them," had given place to a belief that absolute rest was to be found all around us in an aether which permeated all bodies. What was striking about the hypothesis was its implication—either that we could not measure the velocity relative to ourselves of a medium which surrounded us on all sides, or else that no such medium existed.

The hypothesis demanded detailed and exhaustive examination. It was for the mathematician to test whether the hypothesis was in opposition to known and established laws of physics, and to this task Einstein, Lorentz and others set themselves. If a single firmly established law proved to be in opposition to the hypothesis, then of course the hypothesis would require to be abandoned. It was unlikely that such an event would occur among the well-established laws, for if it did, the phenomena governed by that law would enable direct measurement to be made of the earth's velocity through the aether, a measurement which had so far eluded all attempts of experimenters. It was among the more obscure and less well-established laws, if anywhere, that discrepancies were to be looked for.

It is impossible here to give a complete account of the many tests to which the relativity hypothesis has been subjected. The result of all can be summed up in one concise and quite general statement:—Wherever the hypothesis of relativity has appeared to be in conflict with known or suspected natural laws, further experiment, where possible, has, without a single exception, shown the laws to be erroneous, and has moreover shown the alternative laws suggested by the hypothesis of relativity to be accurate. It is only in somewhat exceptional cases that the hypothesis of relativity of itself suffices to determine fully the form of a natural law; these cases constitute the most striking triumphs of the theory. As instances may be mentioned the determination of the law connecting the mass of an electron with its velocity; of the law expressing the velocity of light through a transparent medium in motion (Fizeau's water-tube experiment); and of the formulae for the magnetic forces on moving dielectric media (experiments of Eichenwald and H. A. Wilson).¹

Before passing on from the general statement which has been made, particular mention must be made of one special case. A natural law which was at an early stage seen to be in conflict with the hypothesis of relativity was Newton's famous law of gravitation—namely, that every particle of matter attracts every other particle with a force proportional to the product of the two masses, and to the inverse square of their distance apart. Either, then, Newton's great law had to be abandoned, or else the hypothesis of relativity had to be discarded, in which case it would immediately become possible, in theory at least, to determine the earth's velocity through space by gravitational means. It is the choice between these two alternatives that has led to the most surprising developments of the theory of relativity; and to these we shall return later.

¹ For references to the original papers dealing with these and other tests of the hypothesis of relativity see Cunningham, *The Principles of Relativity*, or J. H. Jeans, *Mathematical Theory of Electricity and Magnetism* (4th ed.).

Space and Time.—The hypothesis of relativity, as has already been explained, postulates that the phenomena of nature will be the same to any two observers who move relative to one another with any uniform velocity whatever. The hypothesis has been so amply tested as regards all optical and electromagnetic phenomena that no doubt is felt, or can rationally be felt, as to its truth with respect to these phenomena. The hypothesis can be examined and developed in two opposite directions. We may, on the one hand, proceed from the general hypothesis to the detailed laws implied in it; this has already been done, with completely satisfactory results as regards confirmation of the hypothesis. Or we may regard the hypothesis of relativity as being itself a detailed law and attempt to generalize upward to something still wider. It is this possibility which must for the moment claim our attention.

In 1905 Einstein examined in full the consequences of the hypothesis that one simple optical phenomenon—namely, the transmission of a ray of light in free space—was, in accordance with the hypothesis of relativity, independent of the velocity of the observer. If an aether existed, and provided a fixed framework of reference, then light set free at any instant would obviously travel with a velocity which would appear to an observer at rest in this aether to be the same in all directions, and the wave front at any instant would be a sphere having the observer as centre. On the hypothesis of relativity the phenomenon of light transmission must remain unaffected by the motion of the observer, so that the light must appear to a moving observer also, to travel with a uniform velocity in all directions, and thus to the moving observer also the wave front must appear to be a sphere of which he will be the centre. It is, however, quite obvious that the same spherical wave front cannot appear to each of two observers who have moved some distance apart to be centred round himself, unless the use either of the common conceptions of science or of the ordinary words of language is greatly changed. In fig. 2 it is not possible in ordinary language that both O and P should at the same instant be at the centre of the sphere A B C. The change to which Einstein was forced is one which has an intimate bearing upon our fundamental conceptions of the nature of space and time; this change it will be necessary to explain in some detail.

Suppose that two observatories, say Greenwich and Paris, wish to synchronize their clocks, with a view to, let us say, an exact determination of their longitude difference. Paris will send out a wireless signal at exact midnight as shown by the Paris clock, and Greenwich will note the time shown by the Greenwich clock at the instant of receipt of the signal. Greenwich will not, however, adjust their clock so as to show exact midnight when the signal is received; a correction of about .001 second must be made to allow for the time occupied by the signal in traversing the distance from Paris to Greenwich. To turn to mathematical symbols, if t_0 is the time at which a signal is sent out from one station, the time of receipt at a second station is taken to be $t_0 + \frac{x}{c}$, where x is their distance apart, and

c is the velocity of light. This represents the ordinary practice of astronomers, but it is clear that if the earth is travelling through a fixed aether with a velocity u in the direction of the line joining the two observatories, the velocity of transmission of the signal relative to the two observatories will not be c but $c+u$, and the time of receipt at the second station will be $t_0 + \frac{x}{c+u}$. Thus it

appears that it is impossible to synchronize two clocks unless we know the value of u , and that the ordinary practice of astronomers will not, as they expect, synchronize their clocks, but set them at an interval apart equal to

$$x \left(\frac{1}{c} - \frac{1}{c+u} \right)$$

which may, to an approximation, be put equal to $\frac{ux}{c^2}$.

According to the hypothesis of relativity, it is impossible ever to determine the value of u , and so is impossible ever truly

(ii.) The Newtonian law may be untrue in its original form, but may become true when amended so as to conform to the relativity hypothesis.

(iii.) Neither of the foregoing possibilities may be true.

Alternative (i.) was explored by Sir Oliver Lodge, who, assuming the exact truth of the Newtonian law of gravitation, deduced that the observed motion of the perihelion of Mercury could be accounted for if the sun were moving through space with a velocity of about 70 km. a second in a certain direction. This investigation had to be abandoned when it was shown by Eddington that a similar discussion of the motions of the other planets would lead to vastly different values for the sun's velocity. Alternative (ii.) was explored by Einstein and others, but was found to lead to a motion of the perihelion of Mercury equal only to one-sixth part of that actually observed.

Alternative (iii.) remained with its innumerable possibilities. Einstein commenced his attack on the problem by eliminating all possibilities which did not conform to two general principles. The first of these was the principle of relativity. Inasmuch as all physical phenomena except gravitation were believed to conform to this principle, it was natural to try, as a working hypothesis, the effect of assuming gravitation also to conform. The second principle was the so-called principle of equivalence, and this demands a word of explanation.

To our children we explain that an apple falls to the ground because a force of gravitation inherent in the earth's mass impels the apple towards the centre of the earth. Most schoolboys know that this is not quite the whole story; the path of the apple is more accurately determined by supposing the apple to be acted on simultaneously by two forces—a gravitational force of attraction towards the earth's centre and the centrifugal force arising from the earth's rotation. It is only because the earth's rotation is comparatively slow that the conception of an attraction towards the earth's centre gives a tolerably plausible account of the fall of the apple. If the earth rotated at 17 times its present rate objects would not fall, even approximately, towards the earth's centre; they would fall always parallel to the earth's axis, and the inhabitants of the northern hemisphere might explain this as arising from a force of repulsion inherent in the pole star. If the earth rotated many times faster even than this, bodies would fall always perpendicularly away from the earth's axis, and this might be interpreted as arising from a gravitational repulsion residing in the earth's axis.

These illustrations will show that it is easy to confuse acceleration arising from the earth's rotation with gravitational attraction. We may go further and say that it is impossible to distinguish between the effects of gravitational attraction and the effects of acceleration of any kind whatever. Every aeroplane knows this to his sorrow; it is inherently impossible to devise any instrument which shall show the direction of the vertical in an aeroplane, since an acceleration of the aeroplane produces on any instrument whatever, effects which are indistinguishable from those of gravity. From such considerations Einstein was led to his principle of equivalence, which may be enunciated as follows:—

"A gravitational field of force at any point of space is in every way equivalent to an artificial field of force resulting from acceleration, so that no experiment can possibly distinguish between them."

Guided by these two principles—relativity and equivalence—Einstein was led to the view that all gravitational "fields of force" must be illusions. The apparent "force" arises solely from acceleration and there is no other kind of gravitational force at all. In this statement, as in the statement of the principle of equivalence above, the word acceleration is used in its widest sense. Acceleration results not only from change in the amount of a velocity, but from a change in its direction also. For instance a motor-cyclist riding in a circle at a uniform speed of 60 miles an hour will be the subject of an acceleration towards the centre of the circle. He knows that the apparent force so produced is just as real in its effects as gravitation, and to save himself from falling as a result of its influence he must incline the direction of his machine to the vertical.

It is clear that the acceleration or curvature of path which figures as gravitation cannot be an acceleration or curvature in ordinary three-dimensional space. Before the apple starts to fall from the tree there is neither acceleration nor curvature, and yet the apple is undoubtedly acted on by gravitation. Moreover, this three-dimensional space is, as we have seen, different for different observers—it is a subjective and not an objective conception, and the gravitation resulting from such a curvature could not conform to the relativity condition. Einstein was accordingly led to suppose that gravitation arose from curvature in the four-dimensional space, or continuum, in which time formed the fourth dimension. This continuum, as has been seen, is objective and if the path of the particle can also be made objective, the resulting gravitation will conform to the relativity principle. The path of the particle in the continuum is, however, simply its "world line," which we have already had under discussion. This world line is determined by natural laws, and if these are to be objective the specification of the world line must also be objective. There is, however, only one specification of world lines in the continuum which is objective in the sense that the same specification will give the same world lines to observers moving with different velocities. It is that every world line must be so drawn as to represent the shortest path between any two points on it. Mathematically, lines which satisfy this condition are known as *geodesics*. Thus Einstein was led to suppose that world lines must be geodesics in the four-dimensional continuum.

Consider for a moment a page of this volume as presenting a two dimensional analogy of the continuum. The shortest distance between any two points is of course the straight line joining them, so that the geodesics are simply straight lines. These possess no curvature of path and if they formed a true analogy to the geodesics in the continuum there could clearly be no explanation of gravitation of the type we have been contemplating. There is, however, another type of two-dimensional surface. It is represented by the surface of a solid body such as a sphere—say the earth. On the earth's surface the geodesics are the great circles; every mariner or aeronaut who desires to sail the shortest course between two points sails along a great circle. To take a definite instance, the shortest course from Panama to Ceylon is not along the parallel of lat. (about 9° N.) which joins them—the aeronaut wishing to fly the shortest course between the two countries will fly N.E. from Panama, he will pass over England and finally reach Ceylon from the north-west. The reader may rapidly verify this by stretching a thread tightly over the surface of an ordinary geographical globe. Let him now trace out the course on an ordinary Mercator chart, and it will be found to appear very curved indeed—the course of the aeronaut will look surprisingly like that of a comet describing an orbit under the attraction of a sun situated somewhere near the middle of the Sahara.

The reader who performs these simple experiments will understand how Einstein was led to suppose that gravitation could be explained by a curvature inherent in the continuum. The world lines of particles are geodesics but the space itself, so to speak, provides the curvature. The curvature of path is thrust upon the particle by the nature of the continuum, but we, who until recently have been unaware even of the existence of the continuum, have been tempted to ascribe it to the action of a special agency which we have invented *ad hoc* and called "gravitation." According to Einstein, it is no more accurate to say that the earth attracts the moon than to say that the pockets of an uneven billiard table repel the balls.

This train of thought may seem artificial. If so, the reason is that we have not been able to explore the other possibilities which have branched off our main line of thought. In point of fact, Einstein found himself practically limited to the conclusion we have stated. Not only so, but the actual type and degree of curvature in the continuum prove to be uniquely fixed in terms of the masses of the gravitating bodies. Thus Einstein, knowing the mass of the sun, found himself in a position to predict absolutely what the motion of the perihelion of Mercury ought

to be. It was found to be $42.9''$ a century, a figure which agreed with observation to well within the limits of error of these observations. The motions of the other planets, as predicted by the theory of relativity, have also been found to agree with those observed to within the errors of observation. This latter test, however, is not a very stringent one, since the departures from the motion predicted by the Newtonian law are too small to admit of very precise measurement.

Einstein's theory requires us to suppose that the world line of a ray of light also shall be a geodesic in the continuum. In a gravitational field the curvature of the continuum will impose a twist on the path of a ray of light. Einstein found in particular that a ray of light which comes from a distant star and passes near the edge of the sun on its journey ought to be bent, in its passage past the sun, by an angle which should be $1.75''$ if the ray just grazes the sun, and would be less in proportion to the inverse distance from the centre of the sun for other rays. The observatories of Greenwich and Cambridge dispatched expeditions to test this prediction at the eclipse of 1919. It was found that the stars which appeared near to the sun at the instant of eclipse showed an appreciable displacement, as compared with their normal positions, of the type required by Einstein's theory. Exact measurement confirmed that the displacement varied approximately as the inverse distance from the sun, and that the displacement at the limb was sensibly equal to Einstein's predicted value of $1.75''$. The Cambridge observers, hampered by cloudy weather, obtained for this quantity the value $1.61'' \pm 0.30''$. The Greenwich observers obtained a value of $1.98'' \pm 0.12''$, but it has since been pointed out by Prof. H. N. Russell that their photographs indicate a horizontal and vertical scale difference of the order of 1 part in 12,000, almost certainly due to a distortion of the coelostat mirror under the sun's rays, and if the measures are corrected for this the result is brought much closer to the theoretical prediction.

The theory makes one further prediction which admits of experimental test. The atoms of any element, say calcium, may be supposed to be formed according to a definite specification, the terms of which depend neither on the velocity of a particular observer nor on his position relative to the gravitational fields of the universe. It can be deduced that the light received from a calcium atom situated in the intense gravitational field near the sun's surface ought to be of slower period, and therefore of redder colour, than the similar light emitted by terrestrial atoms. To be more precise, the Fraunhofer lines in the solar spectrum ought to show a displacement to the red; this displacement ought to be homologous, and should be of amount 0.008 \AA units at the cyanogen band $\lambda 3883$ at which observations have been chiefly made. Attempts to test this prediction led to strangely discordant results. All observers agreed in finding some effect of the kind predicted, but its amount was always less than the predicted amount, varying from almost nil (St. John, 1917) to nearly the full amount to be expected (Evershed, 1918; Grebe and Buchem, 1919). In 1921 the position with regard to this test still remained one of great uncertainty and confusion.

It will have been seen that the restricted physical theory of relativity introduced a revolution into the foundations of scientific thought by destroying the objectivity of time and space. The gravitational theory has effected a hardly less important revolution by destroying our belief in the reality of gravitation as a "force." The physicist has, however, to deal with other "forces" besides those of gravitation, and the question inevitably arises as to whether these too must be regarded as illusions, arising only from our faulty interpretation of the special metrical properties of the continuum. Prof. H. Weyl has pointed out that the continuum imagined by Einstein, and found to be adequate to explain gravitational phenomena, is not, in respect of its metrical properties, the most general type of continuum imaginable. A further generalization is possible and the new curvatures introduced must of necessity introduce new apparent forces other than gravitational. Weyl's investigation shows that these new forces would have exactly the properties of the electric and magnetic forces with which we

are familiar. Indeed, the predicted forces coincide so completely with known electromagnetic forces that no experimental test of Weyl's theory is possible. Had there been the slightest divergence between the forces predicted by Weyl and those predicted by ordinary electromagnetic theory, experiment could have been asked to decide between the two, but no such divergence exists. It may, however, be said that Weyl's theory makes it highly probable that all forces reduce to nothing more than our subjective interpretations of special properties of the continuum in which we live our lives.

Finally a thought may be given to the position, under the new conceptions introduced by the theory of relativity, of the electromagnetic aether. At one stage in the history of science there was a tendency to fill space with aethers, to the extent almost of one aether for every set of phenomena requiring explanation. That stage passed, and by the end of the 19th century only one aether received serious consideration, the so-called electromagnetic aether of Faraday and Maxwell. This aether gave a plausible mechanical explanation of electrostatic phenomena, although it was more than doubtful whether it could account for the electromagnetic phenomena from which it took its name, and it was comparatively certain that it could not account for gravitation. It gave, however, a satisfactory explanation of the propagation of waves of light—they were simply waves in the aether and travelled with an absolute velocity c determined once and for all by the structure of the aether. On this view it was quite certain that an observer moving through the aether with a velocity u would measure the velocity of light travelling in the same direction as himself as $c-u$. Relativity teaches that this velocity is always precisely c , and this in itself disposes of the aether of Faraday and Maxwell. Whether any new aether will be devised to replace it remains to be seen, but none appears to be necessary. Any aether which can be imagined would appear to depend upon an objective separation of time and space. Relativity does not deny that such an objective separation may, in the last resort, really exist, but it shows that no material phenomena are concerned with such a separation. By a very slight turn of thought, the primary postulate of relativity may be expressed in the form that the material world goes on as though no aether existed.

To the relativist the essential background to the picture of the universe is not the varying agitation of a sea of aether in a three-dimensional space but a tangle of world lines in a four-dimensional space. Moreover, it is only the intersection of the world lines that are important. An intersection at a point in the continuum represents an event, while the part of a world line which is free from intersections represents the mere uneventful existence of a particle or a pulse of light. And so, since our whole knowledge of the universe is made up of events, it comes about that the tangle of world lines may be distorted and bent to any degree we please; so long as the order of the intersections is not altered, it will still represent the same universe. And so the last function of the aether, that of providing a scale of absolute measurements in space, becomes a superfluity. To the physicist who urges that space measurements without an underlying aether become meaningless, the relativist can reply that time-measurements without an underlying "time-aether" are equally meaningless. A "time-aether" has never been regarded as a necessity, and the relativist feels that the "space-aether" has no greater claim to retention. (J. H. JE.)

RENEVIER, EUGÈNE (1831-1906), Swiss geologist (see 23.98), died at Lausanne May 4 1906.

RENNENKAMPF, PAUL (1854-1918), Russian general, was born in 1854 and entered the army in 1873. On passing out of the Academy of the General Staff in 1882, he was appointed to the General Staff. From 1895 to 1899 he commanded a regiment and in 1900 he was promoted to the rank of general. In the war with China in 1900 he distinguished himself by his resolute action when commanding a column in Manchuria. In the war with Japan 1904-5 he commanded first a Cossack division, and later large forces of all arms, and again won distinction by his energy. From 1903 to 1913 he was a corps

commander and in 1913 he was appointed to command the troops of the Vilna Military District. At the beginning of military operations in Aug. 1914 he commanded the I. Army which invaded Eastern Prussia. His inaction during the battle of Tannenberg, where the neighbouring army of Samsonov was destroyed Aug. 26-29, was a bitter disappointment, and, by the masses of the people, he was even accused of treachery. Personally brave, daring in small actions, Rennenkampf, as an army commander, showed himself in the strategic sphere alternately rash and timid, owing to his inability to grasp the situation as a whole. At the beginning of 1915 he was recalled from his duties of army commander, and later, under the pressure of public indignation, he was dismissed from the service. In 1918 he was killed by the Bolsheviks.

RENNER, KARL (1870-), Austrian politician, was born on Dec. 14 1870, the son of a peasant, at Unter-Tannowitz, Moravia. He studied law at the university of Vienna, occupying himself especially with questions of administration, and early attached himself to the Social Democratic party. He became an official in the library of the *Reichsrat*, and under the pseudonyms of "Synopticus" and "Rudolf Springer" showed a fertile literary activity, especially in connexion with the problems of the Austrian State, whose existence he justified on geographical, economic and political grounds. On the nationality question he upheld the so-called "personal autonomy," on the basis of which the super-national state should develop, and thereby influenced the programme and tactics of the Social Democratic party in dealing with it. As a theorist he was reckoned as one of the leaders of Neo-Marxism. He had been a deputy since 1907 and after the revolution of Oct. 1918 he became state chancellor of the republic of Austria, headed the Austrian peace delegation at St. Germain, and took over, after Otto Bauer's retirement, the Ministry of Foreign Affairs, which he conducted from the time of the retirement of the Coalition Cabinet in the summer of 1920 until the new elections in Oct. 1920. His principal works are:—*Grundlagen und Entwicklungsziele der österreichisch-ungarischen Monarchie* (1906); *Der Kampf der österreichischen Nationen um den Staat; Marxismus, Krieg und Internationale*.

RENOIR, AUGUSTE (1841-1919), French painter (see 23.101), died on the Riviera Dec. 3 1919.

REPARATION COMMISSION: see PEACE CONFERENCE; also 34.123 and 246.

REPIN, ILJA JEFIMOVICH (1844-1918), Russian painter (see 23.105), died at Knokkala, on the Finnish frontier, July 17 1918.

REPLIER, AGNES (1858-), American writer, was born in Philadelphia April 1 1858. She was of French extraction and was educated at the Sacred Heart Convent at Torresdale, near Philadelphia. She was one of America's chief representatives of the discursive essay, displaying wide reading and apt quotation. Her writings contain much sound literary criticism as well as caustic comments on contemporary life. These characteristics were already apparent in the first essay which she contributed to the *Atlantic Monthly* (April 1886), entitled "Children, Past and Present." In 1902 the university of Pennsylvania conferred upon her the degree of Litt.D. She was the author of *Books and Men* (1888); *Essays in Miniature* (1892); *Essays in Idleness* (1893); *Philadelphia—the Place and the People* (1898); *Compromises* (1904); *In our Convent Days* (1905); *Americans and Others* (1912); *Counter-Currents* (1915).

RESZKE, EDOUARD DE (1855-1917), operatic singer (see 23.201), died at Garnet, Poland, May 29 1917.

RÉVILLE, ALBERT (1826-1906), French Protestant theologian (see 23.224), died in Paris Oct. 25 1906. His son, JEAN RÉVILLE (b. 1854), died in 1908.

REYER, ERNEST (1823-1900), French musical composer (see 23.225), died at Lavandou-sur-Huyères Jan. 15 1909.

REYNOLDS, OSBORNE (1842-1912), British engineer, was born at Belfast in 1842. He was educated at Dedham grammar school and at Cambridge, and in 1868 became professor of engineering at Owens College, Manchester, holding that post

for nearly 40 years. He was elected F.R.S. in 1877. He was the author of over 70 papers on mechanics and physics published in the transactions of learned societies, notably *Sub-Mechanics of the Universe*, issued by the Royal Society, whose gold medal he won in 1888. (For his work see 3.581; 5.64; 8.783; 14.61; 22.806; 25.444; 28.428.) He died at Watchet, Som., Feb. 21 1912.

REYNOLDS, STEPHEN (1881-1919), English author, was born at Devizes May 16 1881. Educated at Manchester University and the École des Mines at Paris, he became sub-editor of an Anglo-French review in 1902 and the following year began an association with the Woolley brothers, fishermen of Sidmouth, which lasted for some years. He thus familiarized himself with fishing and the fisherman's point of view so far as to become a recognised authority on the subject and a medium of communication between fishermen and the Government. He was a member of the committee of inquiry into Devon and Cornwall Fisheries (1912), and of the departmental committee on Inshore Fisheries (1913), and in that year he was appointed adviser on Inshore Fisheries to the Development Commission. In 1914 he became also resident inspector of fisheries for the S.W. area. His publications included *A Poor Man's House* (1908); *Alongshore* (1910); *The Lower Deck, the Navy and the Nation* (1912); as well as a novel, *The Holy Mountain*, (1909) and a volume of tales. He died at Sidmouth Feb. 14 1919.

RHODE ISLAND (see 23.248).—The pop. of the state in 1920 was 604,397; in 1910, 542,610; an increase for the decade of 61,787, or 11.4 per cent. Rhode Island was still in 1920 the most densely populated state, having 366.4 inhabitants to the sq. m. (1910, 508.5). Every Federal census since 1790 has shown an increase in density, and at a rate faster than that of the United States as a whole.

The percentages of urban and rural pop. were in 1920: urban, 97.5%; rural, 2.5%; in 1910: urban, 96.7%; rural, 3.3%. The following are the cities of Rhode Island having a pop. of over 20,000 in 1920 and their percentage of increase in the decade 1910-20:—

	1920	1910	Increase per cent
Providence	237,595	224,326	5.9
Pawtucket	64,248	51,622	24.5
Woonsocket	43,496	38,125	14.1
Newport	30,255	27,149	11.4
Cranston	29,407	21,107	39.3
Central Falls	24,174	22,754	6.2
East Providence	21,793	15,808	37.9

The proportion of native-born in 1915 (state enumeration) was 68.8%; of foreign-born, 31.2%. The foreign-born whites numbered in 1920, 173,366, a decrease of 2.6% from 178,025 in 1910. During the 10 years there has been a steady change in the proportions of the various foreign elements in the population. Up to 1910 the largest foreign-born element was Irish. In 1920 the Irish were numerically inferior to the British and English-Canadian, the Italian, and the French-Canadian. There has been a remarkable increase in the number of Italian, Portuguese and Polish immigrants, and a noticeable influx of Armenians and Syrians. "Foreign stock," i.e. foreign-born and native-born of foreign parents, constituted, in 1915, 63.3% of the whole population.

Agriculture.—There has been a decline in farm acreage of 29.3% in 30 years to 331,600 ac. in 1920, and an even greater decline, 51.2%, in improved acreage to 132,855 ac. in 1920. The number of farms has fallen from 5,292 in 1910 to 4,083 in 1920. On the other hand there has been a rise in both the aggregate and the average value of farms, and in the value of crops (value of land and improvements, 1900, \$26,989,189; 1920, \$33,636,766; value of crops, 1909, \$2,986,816; 1919, \$5,340,378).

Fisheries.—Fishing has, on the whole, declined in relative importance. The shell-fish industry suffered severe loss, owing to the pollution of the Providence river and the upper waters of Narragansett Bay. From 1907 to 1920 the leased oyster grounds declined from 21,000 to 7,000 ac.; the state rentals, from \$136,000 to \$40,000; and the output during the oyster season from 10,000 gal. daily to 2,000 gallons. In 1920 the Commissioners of Shell Fisheries reported: "The Providence river has been practically destroyed as a suitable place for the production or growth of shell-fish as food," the result of contamination.

Manufactures.—Rhode Island is preëminently a manufacturing state. In 1914 it ranked 19th among the states in the value of its manufactures. The number of persons engaged in manufacturing and mechanical pursuits nearly doubled in 20 years (1900, 101,162; 1910, 156,808; 1920, 196,205). The number of factories increased from 1,678 in 1900 to 2,829 in 1919; the capital invested in manu-

facturing from \$183,784,587 in 1900 to \$304,595,000 in 1914; and the value of all manufactured products from \$184,074,378 in 1900 to \$346,962,500 in 1916. Wages paid to factory employees in 1914 totalled \$58,784,000; value added to products by manufacture, \$116,030,000. Children under 16 years employed in factories numbered, in 1920, 7,243, of whom nearly 5,000 were in textile mills. The effect of the World War upon child labour in Rhode Island may be seen from the following statistics: in 1915 children under 16 years constituted 3.16% of all the factory operatives; in 1918, 4.44%; in 1919, 3.96%; in 1920, 3.69%. Textiles still held in 1920 the first place among the manufactures of the state, employing 83,204 persons. From 1910 to 1920, woolen and worsted mills increased in number from 88 to 103 (with 463,342 spindles and 9,304 looms); in employees, from 24,924 to 29,500; in value of products, from \$74,600,000 to \$90,000,000. Cotton mills increased in number from 106 to 130 (with 2,595,395 spindles); in employees, from 28,786 to 37,382; and in value of products, from \$50,313,000 to \$67,500,000. Over 7,000 were persons employed in bleaching and finishing, 6,000 in the manufacture of silk and silk goods, and nearly 3,000 in the manufacture of hosiery and knit goods. The combined value of the products of these factories exceeded \$20,000,000. Webbing and braid were also produced in large quantities; and in recent years tire fabrics have become an increasingly important article of manufacture. Third among the industries of Rhode Island in 1920 were the machinery and metal trades, with 25,197 employees, and products valued at \$45,000,000. In the manufacture of jewelry and silverware Rhode Island ranked first among the states. In 1914 the value of the jewelry produced was more than one-fourth of the total for the whole United States. The number of persons employed in making jewelry, silversmithing, reducing and refining gold and silver in 1920 was 14,052, in 322 establishments; and the value of the product was estimated at \$37,500,000.

Transportation.—The railway mileage within the state in 1920 was 209.49 m., electric and street railways, 351.5 miles. The construction of a branch of the Grand Trunk Railway system from Palmer, Mass., to Providence was projected in 1910; but work was suspended in Nov. 1912, and has not been resumed. Considerable sums have been spent by the Federal Government for the deepening of the channel of Narragansett Bay, for harbour improvement at Providence, Newport, Westerly and Pawtucket, and for the construction of harbours of refuge at Block I. and Pt. Judith. The foreign imports of the customs district of Rhode Island amounted in 1920 to \$8,252,046. Foreign and domestic commerce passing through Narragansett Bay in 1914 amounted to \$320,195,277.

Finance.—The position of the state, Dec. 31 1920, was: assessed valuation, \$988,061,741; rateable wealth, \$1,745,715,365 (about \$2,800 per capita); receipts, \$6,909,172; expenditures, \$6,187,173; bonded debt, \$10,832,000; sinking fund, \$1,631,917. June 30 1920 there were in Rhode Island three state banks, 17 national banks, 13 trust companies, 15 savings banks, and 10 other institutions for savings and loans; with total resources of \$416,339,951. From June 30 1918 to June 30 1920 the assets of the state banks increased 47% of the trust companies, 21%; of the savings banks, 20%; and of the national banks, 11%. Deposits in the savings banks, June 30 1920, were \$113,200,366, an average of \$630 per account. The average savings deposit in 1918 (\$582.95) was the largest in any state.

Charitable and Penal Institutions.—In 1917 the Board of Control and Supply and the Board of Charities and Corrections were superseded by a State Penal and Charitable Commission. The number of the inmates in the institutions under the supervision of the Commission was, in 1919, 3,241 (468 less than in 1918), and the amount expended was \$1,189,956. The budget for 1921 called for \$1,562,396, to which should be added about \$21,000 in aid of various private charitable organizations.

Education.—The total school population (ages 5 to 19) in 1920 was 123,705, of whom 106,142, or 85.5%, were in school. There were 2,525 in public schools; 20,690 in parochial schools; and 1,927 in private schools. The total expenditure for education in 1920 was \$4,493,772, of which \$999,850 was contributed by the state, the remainder by the towns. In addition to its expenditure for primary and secondary instruction and for normal training, the state annually votes modest subsidies for the R.I. State College; the R.I. School of Design; the R.I. College of Pharmacy; the R.I. Historical Society; the Newport Historical Society; and about 20 public libraries, with over 700,000 volumes. In April 1920 the name of the State Normal school was changed to the R.I. College of Education; the enrolment of the institution in 1920-1 was 774 students and 57 instructors; state appropriation, \$86,000. The state also maintains observation and training courses in various schools, and likewise makes an annual grant of \$5,000 to Brown University in support of graduate courses in education. The R.I. State College at Kingston had, in 1920-1, 345 students and 55 instructors, an income of \$168,099, and buildings valued at \$500,800. The number of students, however, has doubled in size, since 1910, the number of students having increased from 223 to 1,856; instructors from 59 to 108; funds from \$186,310 to \$2,849,322; buildings from \$220,000 to \$430,000. The museum is considered the most valuable in New England outside of Boston. Providence College (Roman Catholic) was chartered in 1917, and opened for instruction in 1919, under the direction of the Dominican Order. In 1920, 1920-1, 1921-2, 1922-3, 1923-4, 1924-5, 1925-6, 1926-7, 1927-8, 1928-9, 1929-30, 1930-1, 1931-2, 1932-3, 1933-4, 1934-5, 1935-6, 1936-7, 1937-8, 1938-9, 1939-40, 1940-1, 1941-2, 1942-3, 1943-4, 1944-5, 1945-6, 1946-7, 1947-8, 1948-9, 1949-50, 1950-1, 1951-2, 1952-3, 1953-4, 1954-5, 1955-6, 1956-7, 1957-8, 1958-9, 1959-60, 1960-1, 1961-2, 1962-3, 1963-4, 1964-5, 1965-6, 1966-7, 1967-8, 1968-9, 1969-70, 1970-1, 1971-2, 1972-3, 1973-4, 1974-5, 1975-6, 1976-7, 1977-8, 1978-9, 1979-80, 1980-1, 1981-2, 1982-3, 1983-4, 1984-5, 1985-6, 1986-7, 1987-8, 1988-9, 1989-90, 1990-1, 1991-2, 1992-3, 1993-4, 1994-5, 1995-6, 1996-7, 1997-8, 1998-9, 1999-00, 2000-1, 2001-2, 2002-3, 2003-4, 2004-5, 2005-6, 2006-7, 2007-8, 2008-9, 2009-10, 2010-11, 2011-12, 2012-13, 2013-14, 2014-15, 2015-16, 2016-17, 2017-18, 2018-19, 2019-20, 2020-21, 2021-22, 2022-23, 2023-24, 2024-25, 2025-26, 2026-27, 2027-28, 2028-29, 2029-30, 2030-31, 2031-32, 2032-33, 2033-34, 2034-35, 2035-36, 2036-37, 2037-38, 2038-39, 2039-40, 2040-41, 2041-42, 2042-43, 2043-44, 2044-45, 2045-46, 2046-47, 2047-48, 2048-49, 2049-50, 2050-51, 2051-52, 2052-53, 2053-54, 2054-55, 2055-56, 2056-57, 2057-58, 2058-59, 2059-60, 2060-61, 2061-62, 2062-63, 2063-64, 2064-65, 2065-66, 2066-67, 2067-68, 2068-69, 2069-70, 2070-71, 2071-72, 2072-73, 2073-74, 2074-75, 2075-76, 2076-77, 2077-78, 2078-79, 2079-80, 2080-81, 2081-82, 2082-83, 2083-84, 2084-85, 2085-86, 2086-87, 2087-88, 2088-89, 2089-90, 2090-91, 2091-92, 2092-93, 2093-94, 2094-95, 2095-96, 2096-97, 2097-98, 2098-99, 2099-00, 2100-01, 2101-02, 2102-03, 2103-04, 2104-05, 2105-06, 2106-07, 2107-08, 2108-09, 2109-10, 2110-11, 2111-12, 2112-13, 2113-14, 2114-15, 2115-16, 2116-17, 2117-18, 2118-19, 2119-20, 2120-21, 2121-22, 2122-23, 2123-24, 2124-25, 2125-26, 2126-27, 2127-28, 2128-29, 2129-30, 2130-31, 2131-32, 2132-33, 2133-34, 2134-35, 2135-36, 2136-37, 2137-38, 2138-39, 2139-40, 2140-41, 2141-42, 2142-43, 2143-44, 2144-45, 2145-46, 2146-47, 2147-48, 2148-49, 2149-50, 2150-51, 2151-52, 2152-53, 2153-54, 2154-55, 2155-56, 2156-57, 2157-58, 2158-59, 2159-60, 2160-61, 2161-62, 2162-63, 2163-64, 2164-65, 2165-66, 2166-67, 2167-68, 2168-69, 2169-70, 2170-71, 2171-72, 2172-73, 2173-74, 2174-75, 2175-76, 2176-77, 2177-78, 2178-79, 2179-80, 2180-81, 2181-82, 2182-83, 2183-84, 2184-85, 2185-86, 2186-87, 2187-88, 2188-89, 2189-90, 2190-91, 2191-92, 2192-93, 2193-94, 2194-95, 2195-96, 2196-97, 2197-98, 2198-99, 2199-00, 2200-01, 2201-02, 2202-03, 2203-04, 2204-05, 2205-06, 2206-07, 2207-08, 2208-09, 2209-10, 2210-11, 2211-12, 2212-13, 2213-14, 2214-15, 2215-16, 2216-17, 2217-18, 2218-19, 2219-20, 2220-21, 2221-22, 2222-23, 2223-24, 2224-25, 2225-26, 2226-27, 2227-28, 2228-29, 2229-30, 2230-31, 2231-32, 2232-33, 2233-34, 2234-35, 2235-36, 2236-37, 2237-38, 2238-39, 2239-40, 2240-41, 2241-42, 2242-43, 2243-44, 2244-45, 2245-46, 2246-47, 2247-48, 2248-49, 2249-50, 2250-51, 2251-52, 2252-53, 2253-54, 2254-55, 2255-56, 2256-57, 2257-58, 2258-59, 2259-60, 2260-61, 2261-62, 2262-63, 2263-64, 2264-65, 2265-66, 2266-67, 2267-68, 2268-69, 2269-70, 2270-71, 2271-72, 2272-73, 2273-74, 2274-75, 2275-76, 2276-77, 2277-78, 2278-79, 2279-80, 2280-81, 2281-82, 2282-83, 2283-84, 2284-85, 2285-86, 2286-87, 2287-88, 2288-89, 2289-90, 2290-91, 2291-92, 2292-93, 2293-94, 2294-95, 2295-96, 2296-97, 2297-98, 2298-99, 2299-00, 2300-01, 2301-02, 2302-03, 2303-04, 2304-05, 2305-06, 2306-07, 2307-08, 2308-09, 2309-10, 2310-11, 2311-12, 2312-13, 2313-14, 2314-15, 2315-16, 2316-17, 2317-18, 2318-19, 2319-20, 2320-21, 2321-22, 2322-23, 2323-24, 2324-25, 2325-26, 2326-27, 2327-28, 2328-29, 2329-30, 2330-31, 2331-32, 2332-33, 2333-34, 2334-35, 2335-36, 2336-37, 2337-38, 2338-39, 2339-40, 2340-41, 2341-42, 2342-43, 2343-44, 2344-45, 2345-46, 2346-47, 2347-48, 2348-49, 2349-50, 2350-51, 2351-52, 2352-53, 2353-54, 2354-55, 2355-56, 2356-57, 2357-58, 2358-59, 2359-60, 2360-61, 2361-62, 2362-63, 2363-64, 2364-65, 2365-66, 2366-67, 2367-68, 2368-69, 2369-70, 2370-71, 2371-72, 2372-73, 2373-74, 2374-75, 2375-76, 2376-77, 2377-78, 2378-79, 2379-80, 2380-81, 2381-82, 2382-83, 2383-84, 2384-85, 2385-86, 2386-87, 2387-88, 2388-89, 2389-90, 2390-91, 2391-92, 2392-93, 2393-94, 2394-95, 2395-96, 2396-97, 2397-98, 2398-99, 2399-00, 2400-01, 2401-02, 2402-03, 2403-04, 2404-05, 2405-06, 2406-07, 2407-08, 2408-09, 2409-10, 2410-11, 2411-12, 2412-13, 2413-14, 2414-15, 2415-16, 2416-17, 2417-18, 2418-19, 2419-20, 2420-21, 2421-22, 2422-23, 2423-24, 2424-25, 2425-26, 2426-27, 2427-28, 2428-29, 2429-30, 2430-31, 2431-32, 2432-33, Inhabitants.—At the census of May 2, 1921 the white inhabitants of Southern Rhodesia numbered 33,621, compared with 23,606 in 1911 and 12,596 in 1904. In 1921 males numbered 18,987 and females 14,634. The increase per cent. in the male pop. in the 10 years was 21.87, that of the female pop. 82.23. The natives in 1921 numbered 845,593, compared with 744,559 in 1911 and 591,493 in 1904. Asiatics in 1921 numbered 1,250 and the coloured pop. 1,997. Salisbury and Bulawayo, the chief towns, had in 1921 a white pop. of 5,634 and 6,830 respectively. Gwelo (white pop. 1,148) and Umtali (white pop. 1,874) were made municipalities in 1914, and Gatooma was made a municipality in 1917. All these places have most of the amenities of European towns.

In Northern Rhodesia the white in 1911 numbered about 1,500, and in May 1921 3,585, of whom 2,223 were males and 1,326 females. A considerable proportion of the white residents are officials and missionaries and their families. The native pop. in 1920 was estimated at 928,000.

Communication.—Little was done during 1910-21 to extend communication in Rhodesia itself, but from Sakania on the Rhodesian-Belgian Congo frontier the railway was continued through Katanga with the result that the valuable mineral output of that region was carried over the Rhodesian lines. The completion of the line from Zeerust (Transvaal) to Mafeking (Cape province) shortened the distance between Rhodesian stations and Johannesburg by 250 miles and enabled Durban to compete for the Rhodesian trade. On the completion in 1913 of the line through the northern Transvaal to the Limpopo at Messina, proposals were made to bridge the gap left—some 130 m.—between the Union railways and the West Nicholson branch of the Rhodesian system. As the bridging of the gap would place Lourenço Marques as closely in touch with Bulawayo as is Beira (its existing port), there was much opposition from interested parties to the building of the line and construction had not begun in 1921. Among other projects the most important was the so-called Sinoia-Kafue cut-off, to give Salisbury and Beira a much shorter line to Northern Rhodesia and Katanga. The line in 1921 had been built as far as Sinoia only. In south-eastern Rhodesia the branch line from Gwelo had been extended to Victoria.

There was a good deal of road-making, the largest piece of work being the cutting of a road—400 m. long—through the bush from Broken Hill to Lake Tanganyika. This was done for military reasons during the campaign in German East Africa. In 1919 aerodromes were made at Bulawayo and other stations on the Cairo-Cape route.

For the year ended Sept. 30 1919 the report of the Rhodesian Railways Ltd. showed that the gross revenue was £1,058,000; expenditure £568,000 and net earnings £490,000. For the year ended Sept. 30 1910 the corresponding figures were £789,990, £362,000 and £427,000 respectively. The gross revenue of the Beira-Salisbury and Kalomo-Broken Hill sections of the Mashonaland Railway Co. for 1918-9 was £647,000; expenditure £367,000 and net earnings £280,000, compared with £502,000, £184,000 and £317,000 respectively in the year ended Sept. 30 1910.

Agriculture.—At the end of 1919 the area under crops, excluding vegetable gardens and land cultivated by the natives for their own benefit, in Southern Rhodesia was 215,276 ac., of which 177,470 ac. were under maize. In 1911 the area under crops was 132,105 acres. The production of wheat increased in Mashonaland, the quantity produced in 1919 (13,432 bags) being double the amount of the output five years previously. Tobacco became one of the principal crops, the production of leaf in 1919-20 being about 2,500,000 pounds. Cotton-growing had not got beyond the experimental stage in 1921. The citrus industry made headway and considerable quantities of oranges, etc., are now exported. Over 6,000 boxes were shipped to the United Kingdom in 1920.

The Mazoe dam, which has an effective storage capacity in a normal season, after allowing for evaporation, of 4,000,000,000 gal., was completed in March 1920. This dam enables sufficient water to be stored for the irrigation of 6,000 ac. with 2½ ft. per annum.

Cattle-breeding in the decade 1911-21 became one of the leading industries of Rhodesia. By the importation of pedigree bulls the native breed was steadily improved. In 1919 29,510 head of cattle was exported by rail or on the hoof to the cold-storage works in the Union or to Portuguese East Africa and the Belgian Congo. By the end of 1919 the number of cattle owned by Europeans (673,431) exceeded the number belonging to the natives. In 1910 the total (European and native owned) was 371,000. The Liebig Co. acquired extensive ranching areas.

In Northern Rhodesia maize and tobacco are the principal crops; wheat was grown under irrigation. Experimental work in the cultivation of wheat and other cereals, fodder plants, fruit and forest trees, fibres and in the investigation of plant diseases was carried on at the Chilanga estate of the B. S. A. Company. Orange-growing was started and a small quantity of cotton grown in the Fort Jameson district adjoining Nyasaland. Large areas of wild rubber exist. Cattle ranching became popular, a good market being found in Katanga for slaughter beasts. Except for the settlement at Fort Jameson, the white residents are mostly concentrated along the railway line from the Victoria Falls to Katanga.

Mining.—Gold is now found in a large variety of formations,

¹ The figures for 1921 are the unaudited return.

including quartz, schists, granite, sandstones, banded ironstones, conglomerates and dolomite.¹ The value of the output steadily increased from £2,566,000 in 1910 to £3,895,000 in 1916, when the yield in ounces was 930,356. The effects of the World War, increased working costs and labour difficulties then brought about a decline and the value of the output had fallen in 1919 to £2,499,000. In 1920 the value of the output went up to £3,056,000, though the yield measured by weight (552,497 oz.) was 40,725 oz. less than in 1919, the rise in value being due to the premiums obtained on sales of gold in 1920. The silver output reached its highest level (211,989 oz.) in 1917 and this was also the case with coal (584,954 tons) and copper (3,911 tons). The largest output of chrome iron ore (88,871 tons) was in 1916. After the end of the World War production was considerably reduced. Asbestos is becoming an important industry, the chief mines being in the Bulawayo and Victoria districts. The output rose from 55 tons in 1908 to 18,823 tons in 1920. Valuable mica deposits are being worked in the Sinoia district, the output in 1920 being 97 tons. Small shipments realized up to £600 per ton. Arsenic (1920, 437 tons) and tungsten (1920, 17 tons) are worked. The output and value of the principal minerals of Southern Rhodesia in 1920 were as follows:—Gold 552,497 oz. (£3,056,549); silver 158,982 oz. (£58,178); copper 3,109 tons (£333,111); chrome iron 60,269 tons (£245,378); coal 578,492 tons (£252,000); asbestos 18,823 tons (£459,572). The total value of mineral production in Southern Rhodesia up to the end of 1920 was £56,164,325.

Northern Rhodesia.—The chief mining centres in Northern Rhodesia are Broken Hill (lead and zinc) and Bwana Mkubwa, near the Congo border (copper). The mineral production in 1920 was as follows, the figures for 1916 being given in parentheses for purposes of comparison:—Gold 569 oz. (719 oz.), value £2,998 (£2,980); silver 5,583 oz. (8,777 oz.), value £706 (£877); copper 145 tons (1,298 tons), value £7,601 (£39,362); lead 16,345 tons (1,392 tons), value £335,000 (£25,121). Up to Dec. 31 1913 13,156 tons of zinc ore, valued at £84,577, had been produced. Mining for this ore then ceased. The total value of the mineral production of the northern territory to Dec. 31 1920 was £1,534,000.

Commerce.—Bacon-making, oil-crushing and soap-making, cheese-making and meat-canning, in addition to creameries and tobacco factories and flour-mills, are established. The following table shows the value of the imports and exports of Southern Rhodesia (exclusive of specie and goods re-exported) in 1910, 1915 and 1919.

	Imports	Exports
1910	£2,786,000	£2,812,000
1915	2,949,000	4,536,000
1919	4,500,000	4,432,000

In Northern Rhodesia the value of imports increased from £168,000 in 1911 to £424,000 in 1919. Exports in 1911 were valued at £107,000 and in 1919 at £452,000.

Revenue.—For the year ended March 31 1911 the revenue of Southern Rhodesia was £773,000 and expenditure £752,000. In 1918-9 the revenue amounted to £961,000 and the expenditure was £858,000. The chief items on the revenue side of the account were: customs duty £298,000; native tax £238,000; posts and telegraphs £100,000; stamps and licences £59,000; income-tax and excess-profits tax £60,000. For the year ending March 31 1920 the revenue was £1,031,000, the expenditure £1,061,000.

The revenue of Northern Rhodesia for the year ended March 31 1912 was £116,000, expenditure being £190,000. In 1919-20 the revenue was £160,000 and expenditure £260,000. Native tax produced (1918-9) £83,000 and customs duty £36,000.

Education.—In Southern Rhodesia in 1919 public expenditure on education was £125,000, the sum of £39,000 being received from fees. At the end of that year there were 77 public schools open, with 4,775 pupils. There are schools of domestic science at Bulawayo and Salisbury. There were 670 native schools, with 38,284 pupils, conducted by missionary bodies, receiving grants in aid.

In Northern Rhodesia in March 1920 European children attending Government schools numbered 222. The Administration established boarding-houses at three centres.

Native Affairs.—No radical change was made in the system of native administration in Southern Rhodesia during 1910-21. The office of Secretary of Native Affairs was filled by the administrator and in each district a commissioner was appointed to direct and protect the natives. The conduct of the white settlers and of the Chartered Co. towards the natives was the subject of strict scrutiny.

¹ The Geological Survey of Southern Rhodesia showed that the majority of the productive gold-mines do not lie in the "schist belt," as previously supposed, but occur in a peculiar granite mass, known as the Mont d'Or granite. Important chrome iron-ore deposits occur in a mass of serpentine and talc-schist, which is related to the Mont d'Or granite in structure and probably in origin. The two masses together, according to the Director of the Geological Survey, Mr. H. B. Maufe (formerly of the Geological Survey of the United Kingdom), constitute an important plutonic complex, which had remained unrecognized until then. The result of the mapping by the Survey was to give a view of the nature of the mineral field totally different from that generally held.

Cases of grave injustice had occurred in the earlier history of the territory and in the period under review further charges were brought against the Company in connexion with the rearrangement of the reserves. Settlers complained that certain lands in native reserves were not being beneficially used by them; the natives made similar complaints. In 1914 a commission under the chairmanship of Mr. (afterward Sir) R. T. Coryndon, then resident commissioner of Swaziland, was appointed by the Colonial Office to inspect and report upon the reserves. The commission concluded its sittings at the end of 1915. It recommended that 5,610,595 ac. should be assigned as additional reserves or extensions to existing reserves, but that 6,673,055 ac. then included within the reserves were not required for that purpose. The total reserve area recommended was 19,428,691 ac., a net reduction of 1,062,460 acres. The Imperial Government decided to accept these recommendations in their entirety in 1917. There was, however, owing to war conditions, delay in adopting the commission's recommendations and attacks were made on the Company's native administration during the greater part of 1919. A Parliamentary White Paper issued in Feb. 1920 contained correspondence between the Aborigines' Protection Society and the Colonial Office on the subject. The charges against the Company were replied to by Lord Buxton (then high commissioner) at Salisbury in Aug. 1919, and by Col. Amery (Under Secretary for the Colonies) in the House of Commons in March 1920. Col. Amery said:—"I believe this House can with confidence endorse the very high testimony of Lord Buxton to the native administration of Rhodesia and the attitude of the civil population generally towards the natives. It is a model, not only in Africa, but for any part of the world where you have the very difficult problem of the white settler living side by side with the native." An Order in Council was passed giving sanction to the Coryndon commission's recommendations. The changes it recommended were gradually carried out and gave rise to little friction. Lord Milner (then Colonial Secretary) set forth in an official despatch that the settlement reached was regarded as final, not only as to the present, but also the future requirements of the natives. To ensure their security of tenure the reserves were vested in the high commissioner for South Africa and would be inalienable save for certain limited purposes and only in exchange for other land.

In Aug. 1921 Prince Arthur of Connaught (the new high commissioner) visited Rhodesia and received a deputation of Matabele. He told them that the decision as to the reserves must stand and that their desire to have a son of Lobenguela recognized as paramount chief could not be granted. "You cannot go back," said the Prince; "you must go forward."

The general condition of the natives of Southern Rhodesia had distinctly improved between 1910 and 1920, and their value as an asset of the country became generally recognized. They were not only producers on their own account, but considerable purchasers of European goods. They paid an annual poll-tax of £1—the only levy made upon them by the administration. In 1911 several ordinances designed to secure better housing, feeding and medical supervision of native labourers outside the reserves came into effect. Steps were also taken to provide agricultural and industrial training, and to cope with cattle disease in the native reserves.

Vaccination and medical examination of natives applying for domestic service was made compulsory and the Bulawayo municipality introduced by-laws providing for a standard of housing accommodation for native servants.

Sleeping sickness along the Congo border of Northern Rhodesia necessitated precautions being taken to prevent its southward extension. Some cases of the disease occurred in the Loangwa valley, but they appeared to be sporadic.

History.—The outstanding feature of the history of the territory in the period 1910-21 was the steady growth of political consciousness on the part of the white residents of Southern Rhodesia. The framers of the constitution of the Union of South Africa left open the door for the adhesion to it of Rhodesia. The ultimate joining of Rhodesia to the Union was taken for granted by most South Africans, but the actual formation of the Union in 1910 seemed to have a contrary effect. It appeared to give a distinct stimulus to the already nascent desire of the Southern Rhodesians for independent self-government. A distinct advance in that direction was made in May 1911, when, by Order in Council, the elected members were given a majority of the seats in the Legislative Council, provision being made for safeguarding the interests of the British South Africa Company.

The legal position at that time was that the British South Africa Co. exercised under its charter sovereign rights subject only to such control as was exercised by the Colonial Office through the high commissioner for South Africa and a Resident in Rhodesia. While the Company's administrative expenditure was by this time slightly exceeded by the revenue, there was no means of making good the heavy losses incurred in opening up the country save by the sale of unalienated lands. Of their

ownership of the land and of their rights of disposal the Company entertained no doubt and this fact had much influence upon the attitude of the directors. Sir Starr Jameson, on resigning towards the close of 1912 his leadership of the Unionist party in the South African Parliament, became president of the Chartered Co. and retained that position until his death in Nov. 1917.¹ The administrator in Southern Rhodesia was Sir William H. Milton, a man of great experience and tact in his dealings both with the white residents and the natives. After over 16 years' service in the territory Sir W. H. Milton resigned in Oct. 1914 and was succeeded by Mr. (afterwards Sir) Drummond Chaplin. But while the administrator and his executive could do much to make the machinery of government work smoothly, there was no power, locally, to shape policy. Disputes arose between the Company and the settlers, who desired a still larger share in the administration. The controversy became acute in view of the fact that in Oct. 1914, under the terms upon which the charter was originally granted, the Crown would have the right to revise its terms with regard to administration. Sir Starr Jameson, Mr. Rochfort Maguire and other representatives of the Chartered Co. visited Rhodesia in 1913, when a further increase was announced in the numbers of elected members of the Legislative Council. As to the financial position the directors said that, as "the land and minerals belonged to the Company," no debt in respect to past deficits would be placed on the country when the Company relinquished its administration. Mr. Maguire described the Company's proposals as a means for bridging the period antecedent to self-government, the ideal towards which, he claimed, the Company was working. In accordance with the promise given, a redistribution ordinance was passed, the elected members being increased to 12, while the number nominated by the Company was fixed at six. At the general election in March 1914 11 of the 12 elected members returned were pledged to support the maintenance—for the time being—of the Company's administration, but, the Council declared, its continuance should not affect the right "at any time" thereafter to the institution of self-government.

The Council in April 1914 definitely challenged the right of the Chartered Co. to the ownership of unalienated lands. The question had been raised in 1908, but was then allowed to drop. It was now recognized as essential that the matter should be settled before the political status of Rhodesia was altered. On behalf of the Rhodesians (i.e. the white settlers) it was claimed that the Chartered Co.'s power to deal with the land was only a delegated right granted by the Crown, and secondly, that if the Company had acquired ownership rights such rights were vested in it "as an administrative and public asset only"; that as a trading body the Company had no title to the land or its revenues. Consequently it was contended that, on the Company ceasing to exercise administrative rights, all unalienated lands should go as public domain to the Government which succeeded it. In July 1914 the claim of the Legislative Council was referred to the judicial committee of the Privy Council for adjudication.

In the meantime it was decided that the Crown should not exercise its right to vary the terms of the charter, which therefore, in virtue of the original provisions, would legally continue unaltered for ten years from Oct. 29 1914. The directors of the Company intimated, however, that they would offer no objection to the earlier establishment of responsible (i.e. self) government should it be deemed necessary and had the concurrence of the British Government. A supplemental charter giving effect to this agreement was issued on March 13 1915.

Meanwhile the outbreak of the World War for a time forced the constitutional question into the background. But the war itself had an important bearing on the political question. The party which desired the indefinite continuance of Chartered Co. rule had nearly disappeared, but an influential party had advocated, as the alternative to self-government, joining the Union of South Africa. This party lost ground as Rhodesians

¹ After Sir Starr Jameson's death Mr. Philip Lyttelton Gell acted as chairman of the board of directors and in Oct. 1920 was appointed president of the Company.

saw what was happening in the Union. The growth of separatist and republican sentiment among the Dutch population, evidenced by the increasing support gained by Gen. Hertzog and particularly the rebellion of 1914, inevitably influenced the political orientation of the almost solid British population of Rhodesia. Disinclination to be swallowed up in the Union and dislike of the introduction of bi-lingualism—a necessary result of Rhodesia becoming a province of the Union—were strongly reinforced by real if perhaps exaggerated fears as to the strength of the Dutch nationalist movement. It was possibly due in part to these developments that a proposal put forward by the Company in 1915 for the amalgamation of Northern and Southern Rhodesia secured (in 1917) a majority in the Legislative Council, though it was not proceeded with.

After an exhaustive inquiry the judicial committee of the Privy Council gave its decision as to the ownership of unalienated lands on July 29 1918. It had had before it not only the claims of the Crown and of the Chartered Co. but those of the natives, whose case was put forward without much evidence that it was being pressed by the natives themselves. The judicial committee reported in favour of the Crown. While, however, it decided that the Company could not claim ownership of unalienated land in Southern Rhodesia, it held that it was entitled to be reimbursed for expenses and outlays of administration in current or past years, and that while it continued to administer Southern Rhodesia it was entitled to apply the proceeds of any sale of land towards the reduction of such expenditure. The Company's exclusive rights to all minerals in the country were confirmed and grants or sales of land made by it were finally legalized.

The next step was to ascertain the amount which would be due to the Company in accordance with the judicial committee's report should the administration of Southern Rhodesia by the Company cease. At the request of the Chartered Co. a royal commission, of which Lord Cave was chairman, was appointed in July 1919 to ascertain the amount which would have been due to it for its administrative expenses if its governing powers had ceased on March 31 1918. The claim filed by the Company was in round figures for £8,000,000 plus interest on the accumulated deficits. The Cave commission took evidence in Rhodesia and its award was issued in Jan. 1920. The commission rejected the Company's claim for interest and fixed the amount due to the Company at £4,435,000, subject to deductions (1) in respect of the value of lands appropriated by the Company for commercial purposes, and (2) the proceeds or value of lands and rights alienated by the Company for considerations other than cash, but plus the value of the public works which might be taken over by its administrative successor, estimated at £830,000.

In the interval the campaign for the grant of self-government had been renewed vigorously in Southern Rhodesia. In view of a coming general election the Legislative Council in May 1919 passed a resolution asking the Colonial office publicly to state what proof of fitness "financially and in other respects" would be considered sufficient to justify the grant of responsible government. Lord Milner (then Colonial Secretary) replied in Aug. that he could not regard the territory in its then stage of development as equal to the financial burden of responsible government, and as there appeared to be no great desire for the inclusion of the territory in the Union he advised that matters should be left as they were until the situation became clearer. This reply caused a good deal of dissatisfaction amongst the advocates of responsible government in Rhodesia. The strength of the movement was shown at the general election in May 1920, when the responsible government party secured 12 of the 13 elective seats in the Legislative Council. The 13th member advocated representative government, a half-measure which Lord Milner had considered impracticable.¹ Owing to the suc-

cesses gained by the Dutch Nationalists at the general election in the Union a few months earlier, opinion in Rhodesia, which, in view of the discouraging attitude of the Colonial Office towards responsible government, had tended to consider more favourably entry into the Union, swung round completely.

The new Legislative Council, at its first meeting in May 1920, passed a resolution praying the Imperial Government to establish responsible government and affirming that—

"The record of the people of Southern Rhodesia establishes that they are capable of fulfilling in the interests of all the inhabitants thereof, irrespective of race, the duties of self-government, and are equally as able to bear the responsibility thereof as other peoples of the Empire to whom the rights of self-government have been granted in the past."

Lord Milner, in a despatch dated Dec. 22 1920, again urged delay. "In principle" he favoured the Rhodesian demand and the Chartered Co. was willing, he said, to be relieved of its responsibilities, but, chiefly on the ground of finance, he proposed that the Company's rule should continue till after the next general election, which in the ordinary course would be held early in 1923. If Rhodesia was then still in the same mind, responsible government could be brought into force not later than Oct. 1924. The elected members of the Legislative Council strongly traversed Lord Milner's arguments and in the end the Colonial Office sought the advice of still another committee.

This committee, of which Lord Buxton, lately governor-general of the Union and high commissioner, was chairman, was appointed on March 7 1921. It acted with promptitude and reported on April 12 following. The electors having so recently expressed their views in favour of the abstract principle of self-government, no advantage would be gained (the committee stated) by another vote on the principle. It recommended therefore that a scheme for responsible government should be drawn up in detail and that by means of a referendum the opinion of the electors on such a definite scheme should be ascertained. If the electors accepted the scheme a proclamation or Order in Council should issue annexing Southern Rhodesia to the dominions of the British Crown and that annexation should be followed by letters patent setting up responsible government. The draft of the constitution, it was suggested, should be drawn up by the Colonial Office in consultation with the elected members of the Legislative Council. Two special provisions were proposed:—

(1) That with regard to the natives the existing authority and control by the high commissioner should be retained; and (2) that control of unalienated land should be exercised through the high commissioner on the advice of a specially created land board. This unalienated land would be charged with the payment of the sum to which the Chartered Co. was entitled under the Cave award.

Many objections might be and were raised to the proposed manner of dealing with the land question, but the elected members of the Legislative Council, under the leadership of Sir Charles Coghlan, accepted the recommendations of the Buxton committee, and Rhodesian delegates were appointed to confer with the Colonial Office.

Meanwhile the general election in the Union in Feb. 1921 had resulted in the defeat of the Dutch Nationalists (though not in any diminution of their voting strength), and it was arranged that, before any irrevocable step was taken, the Rhodesian delegates should consult with Gen. Smuts, the Prime Minister of the Union, as to the alternative plan of Rhodesia becoming a province of the Union. The conference with Gen. Smuts was held at Cape Town in Sept. 1921, before the delegation left for England. It was made clear that if the Rhodesians had changed their minds and desired admission to the Union they would be welcomed, but that the Union would require the ownership of the unalienated lands.

The influenza epidemic of 1918 took a heavy toll of the natives of Rhodesia; the death-roll was estimated at fully 30,000.

A national tribute was paid to Sir Starr Jameson on May 22 1920, when his body, brought from England, where it had been temporarily interred, was given a last resting-place close to the grave of Cecil Rhodes at the World's View in the Matoppos Hills.

¹ The following is an analysis of the returns, one member being elected unopposed. Votes for responsible government 4,663; for representative government 420; for joining the Union of South Africa 814; for continuance of Chartered Co.'s rule 868; total poll (out of 11,098 electors) 6,765.

Survivors of the pioneers Jameson had led into Mashonaland in 1890 were present, and Matabele and Mashona indunas.

Rhodesia's Part in the World War.—The Rhodesian frontiers in 1914 touched German protectorates both on the west and east. The Caprivi "Finger" of German S.W. Africa came up to the Zambezi, west of the Victoria Falls. It was occupied by the Rhodesian forces with little difficulty. On the east a more serious situation was presented, as the Germans, in comparatively strong force, entered Rhodesian territory between Lakes Tanganyika and Nyasa. Aided by and giving aid to the troops of the Belgian Congo, Rhodesian volunteers and the British South Africa police rendered excellent service and held their own against the Germans. Subsequently Rhodesians played a notable part in Gen. Northey's offensive. A small Matabele contingent took part in the fighting, and a combatant battalion was raised from the natives of Northern Rhodesia.

From the first the Rhodesians were not content with the defence of their own territory. A regiment (1st Rhodesian) was raised for service in the 1914 rebellion and in the campaign in S.W. Africa, and early in 1915 another regiment (2nd Rhodesian) was sent to British East Africa, where it gained a deservedly great reputation. Many Rhodesians also enlisted in the British army. Altogether 6,850 Rhodesians (Europeans) were on active service during the war, a number much more than half the adult male population. Rhodesian natives engaged as combatants in E. Africa numbered 2,721, and in addition there were 40,732 "first-line" carriers. Some 152,000 other carriers were engaged on war service in Northern Rhodesia alone.

In the last days of the war (Nov. 2 1918) Gen. von Lettow Vorbeck, with all that was left of the German forces, turning westwards from his pursuers, entered Northern Rhodesia and had reached the Chambezi near Kasama on the day the Armistice was signed in Europe. It was in Rhodesia, therefore, that the last act in the war was played, von Lettow surrendering to the magistrate at Kasama on Nov. 14.

Northern Rhodesia.—The amalgamation of North-Eastern and North-Western Rhodesia was carried into effect on Aug. 17 1911, when Mr. (afterwards Sir) Lawrence Wallace was appointed administrator, a post he held for nearly ten years.¹ The defence of the territory, which had been shared with Nyasaland, had been taken over entirely by the Rhodesian authorities a short time before the amalgamation was carried through. The number of British settlers gradually increased and missionaries did valuable work in training the natives and introducing higher standards among them. The proposal of the Chartered Co. to amalgamate Northern and Southern Rhodesia has already been referred to; the project was dropped. The war, which deeply affected Northern Rhodesia, at first caused marked depression, which was removed by the military expenditure in 1916-7, while the building of the Katanga railway and the mining activity in Katanga brought about a revival. An elective, but purely advisory, council was established in July 1913.

The Chartered Co. was faced with much the same difficulties in Northern as in Southern Rhodesia, nor in the north did revenue meet administrative expenditure. Up to March 31 1919 the deficit was placed at over £1,250,000. As in Southern Rhodesia, the Company claimed the land and minerals and the repayment of administrative deficits, and, equally, the white settlers claimed a greater share in the government, notably control of finance. The consideration of these questions was remitted to the Buxton committee, which in its second report, dated April 29 1921, advised that the legality or otherwise of the Company's claims should be settled by the Privy Council before the future status of Northern Rhodesia was decided. Meanwhile the immediate creation of a legislative council was recommended.

Barotseland (see 3,424).—Barotseland, the S.W. part of Northern Rhodesia, continued to be a native reserve in which Europeans, other than the officials of the Chartered Co. and missionaries and traders approved by the paramount chief, were not allowed to settle. The paramount chief in the exercise of his authority is aided by a *ngambella* (prime minister) and a *kolla* (council); he has no jurisdiction over Europeans. Relations between the Barotse and the Company were satisfactory and missionary enterprise prospered. Distinct interest in education was shown; in 1912 there were 413 scholars at the Barotse national school, 251 being boarders. Lwaniika (see 16,519), who had placed his country under British protection and who won and retained the reputation of an enlightened ruler, died in 1916. He was succeeded by his eldest son Yeta III. (formerly known as Litia). Lealui, the native capital, and Mongu, the residence of the

chief British officials, are both on the Zambezi and seven miles distant from one another.

A list of parliamentary papers relating to Rhodesia is given in the *Colonial Office List*, published annually in London, and annual reports are issued by the British South Africa Company. See also C. Gouldsbury and H. Sheane, *The Great Plateau of Northern Rhodesia* (1911); A. Darter, *The Pioneers of Mashonaland* (1914); the *Report of the Rhodesia Resources Committee* (1921); H. Kolin, *Les lois et l'administration de la Rhodésie* (1913); J. H. Harris, *The Chartered Millions* (1920); and A. S. and G. G. Brown, *The South and East African Year Book and Guide* (annually).

In the preparation of this article the writer is indebted to G. H. Lepper, of the *Trade Supplement to The Times*. (F. R. C.)

RHONDDA, DAVID ALFRED THOMAS, VISCOUNT (1856-1918), British colliery owner and Food Controller in the World War, was a Welshman, born March 26 1856 in Aberdare, grandson of a Monmouthshire yeoman farmer, and son of a Merthyr grocer. His father had prospered in his trade, and in later life enriched himself by speculations in coal. Young Thomas was sent to Clifton College, and afterwards to Caius College, Cambridge, where he graduated as a *senior optime* in the mathematical tripos in 1880, and immediately joined his father in the coal business. He threw himself with great energy and ability both into that and into local Liberal politics; and was so successful in both spheres that he was returned to Parliament for Merthyr in 1888. His extraordinary commercial gifts, his insight, his foresight, and the sympathy which he brought to bear on the conditions of life in the mining industry, soon made him a prominent, and eventually the leading, figure in the industrial world of S. Wales. "D.A.," as he was always called, by his initials, in his own part of the country, endeared himself to the miners by becoming their champion in the 'nineties against the undercutting of prices by middlemen, and by the generous wages which he paid in the collieries under his control; and though in subsequent years he sometimes had differences with the men, he always retained their respect. His business combinations brought him great wealth and culminated in the Cambrian super-combine, which produced some six million tons of steam coal a year. Other important undertakings in which he took a leading share were the Ebbw Vale Steel, Iron and Coal Co., the Rhymney Iron Co., and the Taff Vale Railway Company. So extensive were the ramifications of his interests that, when he accepted office in 1916, the number of directorships from which he retired was no fewer than forty. He had much longer to wait for success in the political than in the commercial field. Though he sat in the House of Commons for Merthyr for 22 years and afterwards for some months for Cardiff, no use was made by the political chiefs of his party of his great capacities for public service, and he therefore retired from Parliament in 1910.

The outbreak of the World War gave him his opportunity. He rendered substantial help to Mr. Lloyd George both at the Exchequer and in the office of munitions, by organizing British industrial resources for war. He took a lead in "capturing German trade," carrying through, for instance, the acquisition of the Sanatogen business. He went to America to complete important war contracts for the Government, and on his return was saved, with his daughter, Lady Mackworth, from the sinking of the "Lusitania." He went back to America almost immediately, and spent seven months there at his own expense, expediting the output of munitions, and regulating and systematizing the prices charged. He was created a baron, as Lord Rhondda, for his services in Jan. 1916; and it was natural that, when Mr. Lloyd George, in forming his ministry in the following Dec., made up his mind to introduce captains of industry into office, he should turn at once to his old ally, who became president of the Local Government Board. His principal business in this post was to prepare for the establishment of the Ministry of Health. Before this was effected he accepted, in June 1917, at the Prime Minister's pressing request, the onerous burden of the Food Controlship, vacated by Lord Devonport. He was no respecter of persons, and immediately took strong steps to put an end to the speculation in the necessities of life which was becoming a public scandal. Then he

¹ On the retirement of Sir L. Wallace (1920), Sir D. Chaplin, the administrator of S. Rhodesia, took charge of N. Rhodesia also.

gradually fixed prices and brought supplies under control, in regard to almost all articles of food except vegetables. Thus he eliminated profiteering in food-stuffs. He also carried through a great decentralization in the administration of his office. But he will be mainly remembered as the author of the system of compulsory food rationing, which was carried out with absolute fairness and impartiality, putting an end to the queues waiting at butchers' and bakers' shops that had rendered the house-keeper's life a burden. As Food Controller, Lord Rhondda ran the biggest trading organization that the world had ever seen. The turnover of his Ministry, apart from the work of the wheat and sugar commissions, amounted to 1,200 millions sterling; with them 2,733 millions sterling. Supplies never failed, and in spite of the German submarine menace there was no hunger in the United Kingdom. His strenuous labours affected his health, and in April 1918 he tendered his resignation; but his work was so invaluable that pressure was put upon him to remain, and he was created a viscount. But the strain was too great. He was attacked by pneumonia and died on July 3. Tributes to his work and to the public loss sustained by his death were paid in both Houses of Parliament.

He married Sybil Margaret Haig, a cousin of Lord Haig, who survived him. They had one child, a daughter, who married Sir Humphrey Mackworth, and who succeeded to the viscounty of Rhondda under a special remainder. (G. E. B.)

RHYS, SIR JOHN (1840–1915), British archaeologist and Celtic scholar, was born in Cardiganshire, the son of a yeoman farmer, and educated at the Bangor Normal College and Jesus College, Oxford. In 1877 he was elected professor of Celtic at Oxford, the first occupant of the newly created chair, and he held that post till his death. In 1895 he became principal of Jesus College. He was Hibbert lecturer in 1886, Rhind lecturer in archaeology at Edinburgh in 1899 and president of the anthropological section of the British Association in 1900. He also served on several royal commissions and was knighted in 1907. He died at Oxford Dec. 16 1915. His published works include *Lectures on Welsh Philology* (1877); *Celtic Britain* (1882, last ed. 1904); *Celtic Heathendom* (1886); *Studies in the Arthurian Legend* (1891); *Celtic Folk-lore* (1901); as well as editions of Welsh texts (with J. G. Evans); *The Welsh People* (with D. B. Jones, 1900), and numerous other papers and studies of Celtic inscriptions and literature. For his work on the Arthurian legend see 12,300, 321, 669.

RIAZ PASHA (c.1835–1911), Egyptian statesman (see 23,281), died June 18 1911.

RIBOT, ALEXANDRE FÉLIX JOSEPH (1842–), French statesman (see 23,285). On Jan. 3 1909 M. Ribot was elected a member of the French Senate, and in Feb. of the following year was offered, but refused, the Ministry for Foreign Affairs in the Monis Cabinet. After the formation of M. Poincaré's Government on Jan. 14 1912 he took the place of M. Léon Bourgeois as president of the committee appointed to deal with the Franco-German treaty, the necessity for the ratification of which he demonstrated. In 1913 he was an unsuccessful candidate for the presidency of the Republic, and on the fall of M. Barthou's Government was invited by President Poincaré to form a Cabinet, but refused. In 1914 he became, with M. Jean Dupuy, leader of the Left Republican group which refused to accept the decisions of the Radical Socialist congress at Pau in Oct. 1913. On June 9 1914 he became prime minister and Minister of Justice, but his Government was bitterly assailed by the Radical Socialists as well as other groups, and only lasted one day.

With the outbreak of the World War M. Ribot's great reputation as an expert in finance and foreign affairs brought him effectively into office. On Aug. 27 1914 he became Minister of Finance in M. Viviani's Ministry of National Defence, an office which he retained when, on Oct. 28 1915, M. Briand succeeded M. Viviani as prime minister. On Feb. 7 1916 he visited London and held a conference with the Chancellor of the Exchequer at the Treasury. When Briand reconstituted his Cabinet, in Dec. 1916, Ribot retained the portfolio of Finance. On the fall of the Briand Ministry (March 17 1917) President Poincaré again

called upon M. Ribot to form a Government, and this time he consented, himself taking the portfolio of Foreign Affairs in addition to the premiership (March 19). In the statement of his policy made to the Chamber on March 21 he declared this to be "to recover the provinces torn from us in the past, to obtain the reparations and guarantees due to France, and to prepare a durable peace based on respect for the rights and liberty of peoples." On July 31, in a reply to the German Chancellor Michaelis, he admitted that in 1917 an agreement had been made with the Tsar to erect the German territories on the left bank of the Rhine into an autonomous state, but denied that there had been any question of their annexation to France. His Government resigned office on Sept. 7; but he accepted the Ministry of Foreign Affairs in the Painlevé Cabinet constituted six days later. He resigned office finally on Oct. 16, owing to the violent criticism of his refusal to fall into the "trap" of the German peace offers.

RIBOT, THÉODULE ARMAND (1839–1916), French psychologist (see 23,286), died in 1916.

RICHARDS, THEODORE WILLIAM (1868–), American chemist, son of the artist William Trost Richards (see 23,299), was born at Germantown, Pa., Jan. 31 1868. He was educated at home, at Haverford College (S.B. 1885), Harvard (A.B. 1886; Ph.D. 1888), Göttingen, Leipzig and the Dresden Technical School. After passing through the various grades of promotion he was appointed professor of chemistry at Harvard in 1901 and was made director of the Wolcott Gibbs Memorial Laboratory in 1912. He was best known for his researches on atomic weights, of which he revised over a score, including that of radioactive lead. The results were generally accepted and for his contributions he received the Nobel Prize in Chemistry in 1914. He also gave much time to physicochemical investigation, especially concerning electrochemistry and chemical thermodynamics, piezochemistry and surface tension. Of these his contributions to atomic compressibility, to the relation between the change of heat capacity and the change of free and total energy, and to the thermodynamics of amalgams have perhaps been the most noteworthy. In 1907 he was Harvard exchange professor at Berlin, and in 1908 Lowell lecturer. He was president of the American Chemical Society (1914), the American Association for the Advancement of Science (1917) and the American Academy of Arts and Sciences (1919). He was a member of the National Academy of Sciences and of most of the European academies. He received hon. degrees from Yale, Harvard, Haverford, Pittsburgh, Clark, Pennsylvania, Oxford, Manchester, Christiania, Prague and Berlin. He was awarded the Davy (1910), Faraday (1911), Willard Gibbs (1912), and Franklin (1916) medals. He was made a member of the National Research Council in 1916.

RICHBOROUGH, a port on the left bank of the mouth of the Stour river, Kent, England, 1½ m. N. of Sandwich, created by the Government during the World War as a base for the expedition of *matériel* to the armies in France and Flanders. The port was planned in June 1916, primarily to relieve Dover of this class of transport. The site chosen consisted of an expanse of marshland through which the Stour flowed as an insignificant stream. The work of construction was under the control of the Inland Waterways and Docks Section of the Royal Engineers, and involved the reclamation of a large tract of swampy foreshore, the widening and deepening of the waterway, the construction of a wharf and jetty nearly a mile in length equipped with powerful cranes and of docks for the building and repair of certain kinds of craft, the erection of acres of hutments and store-sheds, and the laying of some 50 m. of railway sidings. The work was rapidly pushed forward, the workers at one time numbering 20,000; and eventually a self-contained cantonment arose, having its own postal, police, lighting and other services.

The base was operated in a comparatively small way at first but developed into an undertaking of gigantic proportions. At the outset, steamers and barges were used to convey the war material across, until the French ports became congested; then special barges were introduced to take goods direct into the

French canals and thence as close to the firing line as possible. In 1917, speed of transport of material becoming extremely urgent, it was decided to establish a train-ferry service; it came into operation at the end of that year, and the hoisting of cargoes by cranes into barges was largely superseded. Three ferries plied incessantly between Richborough and Calais and Dunkirk, connecting railhead in England with railhead in France. In all, 4,000 barge loads of ammunition, 17,818 guns and limbers, and over 1½ million tons of other stores were sent across.

The ferries, specially designed and built at the works of Sir W. G. Armstrong, Whitworth & Co. of Elswick, were of 363 ft. overall length, 61 ft. beam and 3,654 tons displacement. Four lines of rails on deck gave accommodation for 34 ten-ton wagons carrying an average load of 900 tons. A lifting bridge at the wharf-end, which the ferry approached stern on, enabled accurate connection of rails at all states of the tide, the process of embarking a train requiring ordinarily not more than 15 minutes.

For the protection of the base, a monitor was stationed in Pegwell Bay, and searchlights and heavy and anti-aircraft guns were mounted at many points. Repeated air-raids took place in the vicinity and there were several bombardments from the sea, but Richborough itself was never seriously damaged, the low-lying, featureless character of the marshland probably affording its best protection, more especially at night.

For a year after the Armistice, Richborough continued to deal with vast quantities of material returned from the western front. After the sale and disposal of the surplus military stores and equipment, the port, with the remaining equipment and the fleet of ferries and barges, was sold by the Disposal Board for £1,407,000 (plus the cost up to £40,000 of acquiring the land by the Government) to the Queenborough Development Co., who thus acquired 1,500 ac. of land including 250 ac. that were reclaimed from the swampy foreshore. In 1921, the company proposed to work Richborough as a barge and train-ferry port, ancillary to Queenborough, both centres to serve the requirements of a comprehensive scheme of industrial development in the surrounding districts including the Kent coal-fields.

RICHMOND, SIR WILLIAM BLAKE (1842-1921), English painter (see 23,307), died at Hammersmith Feb. 11 1921.

RICHTER, HANS (1834-1916), Hungarian musical conductor (see 23,312), died at Bayreuth Dec. 5 1916.

RICKETTS, CHARLES (1866-), English artist, was born at Geneva Oct. 2 1866, and was educated in France. In 1889 he became joint editor with Charles Shannon of the *Dial*. In 1896 he founded the Vale press, the output of which was a series of beautifully designed and printed books. Of his pictures, "The Plague" (1911) is in the Luxembourg at Paris, and "Don Juan" (1916) in the National Gallery of British Art. He published *The Prado and its Masterpieces* (1903), *Titian* (1906) and *Pages on Art* (1913).

RICOTTI-MAGNANI, CESARE (1822-1917), Italian general (see 23,316), died at Novara Aug. 4 1917.

RIDDELL, GEORGE ALLARDICE RIDDELL, 1ST BARON (1865-), British newspaper proprietor, was born in London May 25 1865 and educated privately. He became a solicitor in 1888 and settled in practice at Cardiff. There he acquired an interest in the *Western Mail*, and he eventually turned his energies mainly to newspaper management. He went to London and obtained control over the Sunday paper, the *News of the World*, which he developed on popular lines, so that it obtained a huge circulation during the first decade of the 20th century and made its proprietor a very wealthy man. He gradually extended his newspaper connexions, becoming a director also of George Newnes Ltd., Country Life Ltd., and C. Arthur Pearson Ltd., etc. By the year 1909, when he received a knighthood, he had become one of the most influential personalities in the London press, and he took an active part in giving a more efficient organization to various forms of press work, by way of collective action between proprietors themselves and their organs. He was a prominent member of the Newspaper Proprietors' Association at the outbreak of the World War, and owing to his intimate relations with Mr. Lloyd George he gradually became the principal *liaison* between the Press and the Government so far as all matters of public concern were concerned. In this capacity he

represented the British Press at the Peace Conference in 1919 and at all the important Allied conferences subsequently. He was created a baronet in 1918, and raised to the peerage as Baron Riddell of Walton Heath in 1920.

RIDGEWAY, SIR WILLIAM (1853-), British archaeologist, was born in Ireland Aug. 6 1853 and educated at Portlinton, Trinity College, Dublin, and at Caius College, Cambridge, where he was fifth in the classical tripos. In 1880 he was elected fellow of Caius College, Cambridge, and in 1883 became professor of Greek at Queen's College, Cork. In 1892 he returned to Cambridge as professor of archaeology and in 1907 became also Brereton reader in classics. He was made a fellow of the British Academy, and president of the Royal Anthropological Institute (1908-9). He was knighted in 1919. Amongst his publications are *The Origin of Metallic Currency and Weight Standards* (1892); *The Early Age of Greece* (1901); *The Origin and Influence of the Thoroughbred Horse* (1907); *Who were the Romans?* (1907); *The Oldest Irish Epic* (1907), etc. His views on early Greek civilization are described in 12,442; those on the origin of the Romans in 23,616, and those on the horse in 13,717.

RIFLES AND LIGHT MACHINE-GUNS (see 23,325 and 17,237).—Since 1910 there have been few important changes in the design of the military bolt-action rifle. The adoption by many countries of the pointed bullet in lieu of the round-nosed (see 23,328) has led to some strengthening of parts so as to withstand increased chamber pressures. Modifications in the patterns of sights used have also been made here and there.¹ The military rifle had practically reached its zenith before 1914, and the opening of the World War found all armies equipped with rifles of practically equal merit. With the exception that the French continued to use the tube-magazine Lebel rifle and the British and Americans had adopted a shorter barrel than the rest, it might be said that the military rifles of the world were not only equal in merit but similar in design.

This initial equivalence of the opposed rifles continued throughout the war period. Further changes of detail were made. Special rifles were sometimes brought into use for snipers, and fittings were added to the standard service rifle to adapt it as a grenade-thrower and as a sniper's weapon to be used from a deep trench. A heavy single-loader was designed in Germany as an anti-tank weapon, and many changes were made in the ammunition. But the rifle itself, the rifle of the average infantryman, was practically the same at the end of the war as it had been for the past 15 years, or, setting aside the change of bullet type, for twenty-five. The German army of 1918 carried the 1898 rifle, the French the Lebel model 1886-93, the Italians the Mannlicher-Carcano of 1891. The Russian three-line (3-in.) rifle of 1900 was only a modification of the earlier Mousin and Nagant models. The most modern patterns were the British and the American, and these were characterized by having a relatively short barrel, experience in the S. African War having brought "snap shooting" and the consequent need of handiness into relief. Otherwise the elements and their functions were the same, and the dimensions of the same order, in all rifles except the French.

This standstill of progress, in a time when the design of every other kind of weapon was developing at an unprecedented rate, is very remarkable and indicates clearly enough that the military rifle of the conventional type had reached its zenith. As a type, it was not capable of much further development. Designers had already by 1914 produced the first practical models of automatic and semi-automatic arms. Governments were unwilling to re-arm their troops and re-stock their armouries with new models of an obsolescent class. Even the French, whose rifle was not only the oldest but also possessed a type of magazine long discarded by others, made no attempt to replace it by a weapon of the class of the British and American rifles. When war came, all Powers were waiting on events.

In the war itself the machine-gun proper very soon and decisively asserted itself, driving the simple rifle into the back-

¹ For further information see AMMUNITION and SIGHTS.

ground. Further, trench warfare took unforeseen shapes. Grenades, trench mortars, bombs and man-to-man weapons, even clubs and daggers, became normal infantry arms in minor and subordinate combats, while in the battle proper it was the artillery and the machine-gun rather than the firing-line of rifle-armed infantry that governed the issue both in attack and in defence. Thus when, from the latter part of 1916 onwards, the "break-through," with its sequel of free infantry fighting in the background of the broken-through trench systems, became the ideal of tactics, the main infantry weapon was inevitably the machine-gun in some form. And thereupon the machine-gun of the pre-war and early war period began to develop on two distinct lines—the heavy machine-gun with its own rôle and characteristics (see MACHINE-GUN), and the light machine-gun or infantry machine-gun. When this evolution set in, the machine-rifle or automatic rifle (some forms of which were already in use as machine-guns, especially with aircraft) was more or less ready to take up the place allotted to it by tactics.

The light machine-gun or machine-rifle—"infantry machine-gun" is a better designation than either for the class as a whole—is differentiated from the heavy machine-gun, technically and tactically, by being: (a) portable by one man; (b) unprovided with a mounting in the proper sense; (c) as inconspicuous in action or movement as an ordinary rifle; and (d) limited for various reasons to short bursts of fire. On the other side, as against the rifle, it possesses: (a) fire power with which no hand-operated weapon can compete, which indeed is equivalent for some moments at a time to that of the machine-gun proper; (b) an accuracy that, while less than that of the heavy type, is greater than that of the rifle, owing to the absence of trigger jerk and disturbance of the firer by recoil and to the fact that a muzzle support is (usually) provided; (c) ease and certainty in the matter of fire control, a mechanical organ in the hands of one man being far more manageable in the confusion of battle than a squad of extended riflemen. These advantages it gains, of course, at the expense of being more cumbersome, more delicate in mechanism and more expensive than the rifle, and it requires a fuller ammunition supply, or may do so. Further, it lacks one of the characteristics of the old infantry firearm—it cannot serve as the haft of a bayonet, and thus the infantryman ceases, at least for the time being, to be self-sufficing, and infantry organization at its lowest level returns to the 17th-century form, in which a fire element and a shock element are combined in the tactical group rather than in the individual soldier.

The characteristics of automatic rifle and light machine-gun fire, which thus become the most important element of infantry tactics, are briefly as follows. (For convenience, the term "automatic rifle" will be applied to the lighter and that of "light machine-gun" to the heavier members of the class under consideration. The definition by weight adopted in the following article fixes the frontier between the automatic rifle and the light machine-gun at about 20 lb.)

The trajectory of an individual round, whether fired from a rifle, an automatic rifle, a light machine-gun or a heavy machine-gun, is the same for the same ammunition and barrel characteristics, though its relation to the object aimed at will vary to some extent according to steadiness of man or mounting, smoothness or shock of recoil and other factors. On the other hand, the cone or sheaf of fire formed by a group of rounds will be denser with the automatic rifle and denser still with the light machine-gun than it is with a number of rifles representing the same volume of fire per unit time. The grouping of shots is densest of all in the case of the heavy machine-gun fired from a steady mounting.

In proportion, therefore, as the steadiness in position, due to man, ground or mounting, enables an automatic rifle or light machine-gun to group its shots more and more closely, these weapons tend to acquire more and more of the peculiar tactical powers of the heavy machine-gun—the ability: (a) to support close-fighting infantry groups by overhead or acute flanking fire; (b) to pour a direct and intense fire into small but dangerous positions of the enemy, such as machine-gun nests; (c) to enfilade

enemy trenches and harass bridge approaches, cross-roads, and other points of very small area by day or night. It may be admitted at once that no existing light machine-gun and, *a fortiori*, no automatic rifle, is fully capable of (a) and (c), and in particular of overhead fire or fire through intervals between moving or fighting bodies of friendly troops without endangering them. However, in (b) the light machine-gun is ballistically scarcely inferior to the heavy machine-gun. This is its true function, which it performs as a rule better than the heavy, because its mobility allows of a closer approach, easier observation and freer choice of position. The automatic rifle also possesses this power in some measure, but the light weapon of the future to be evolved from the two types must, before unity of type is acceptable, be made quite as capable of performing this tactical service as is the light machine-gun of to-day. At present the automatic rifle seems to be looked upon in some quarters as a weapon to be used normally as a semi-automatic, firing perhaps 50 or 60 rounds where the bolt-action rifle would deliver 10 and to that extent economizing men, reducing confusion, and minimizing casualties in the firing line, but in the last analysis always a rifle in the tactical sense. Its automatic power is reserved for special emergencies, just as, at the beginning of the evolution of the magazine rifle, the magazine was regarded as a reserve of fire power added to a single-loader.

Considering, next, volume of fire, we can safely say that for practical purposes all automatic rifles and light machine-guns have or can be made to have the same rapidity of fire as the heavy machine-gun. The rapidity is purely a function of the design. Whether recoil-operated or gas-operated, the cycle of operations is gone through as fast as the mechanism can take up the motive impulse. On the other hand, the possibility of maintaining the automatic rate for long without damaging the mechanism depends on (a) the solidity of the working parts; and (b) the capacity of the barrel to resist overheating. In both respects the light machine-gun and the automatic rifle are definitely inferior to the heavy. Solidity of working parts and the incorporation in the design of cooling devices both involve deadweight, and it is the designer's first object to eliminate deadweight. In the automatic rifle not only are weights of parts limited but cooling devices are omitted altogether.¹ The possibility of automatic continuous fire is therefore definitely sacrificed. In light machine-guns, on the other hand, the working parts are not greatly different in solidity from those of heavy machine-guns, and some form of cooling device—radiator, circulator or both—is invariably fitted. The extra weight translates itself into greater power of sustained fire. With a positive cooling system, such as the water-jacket of the German L.M.G.08/15, the volume of fire from a light machine-gun is practically equal to that of a heavy, if tactical conditions allow of equal ammunition supply to each. Even the air-cooled guns are capable of delivering many hundred rounds without a pause other than those for changing magazines or belts. It is true that the development of full fire power for several minutes continuously is exceptional and even very exceptional, and it is a matter of opinion how much importance should be attached to this factor relatively to others in the arm of the future. But it seems clear, in any event, that the infantry machine-gun which constitutes the backbone of the attack or the defence ought to possess, at least at the shorter ranges, that power of focussing a storm of bullets on the enemy's machine-gun group, nest, or other centre of effort as soon as it is located. Otherwise the attack or counter-attack must wait for the heavy machine-guns to come well up, or at least to wait till exact information as to the target and the situation has been communicated to them.

This line of reasoning would exclude the automatic rifle altogether but for certain other considerations. The blotting-out by destruction or neutralization of well or strongly posted enemy groups in key positions is not the only function of the infantry machine-gun. It prepares by its fire every local advance of the groups of its own side, whether against or past important hostile nuclei or against simple parties of infantry using fortuitous

¹ Except in the Chauchat, which is on the border line as to weight.

cover, which constitute the rest of the hostile "line." It is the latter which is the average, though not the decisive, incident in mobile warfare, especially when, as in 1918, the principle is to "drive a nail where it will go." In these average incidents sustained fire is the rare exception—German light machine-gun squads in the spring offensive of 1918, for instance, seem to have found that 2,000 rounds daily per L.M.G. sufficed—and mobility is of supreme importance as the machine-guns must push along as fast as the rest of the infantry, and, indeed, get ahead of it in many cases. This is a strong, and indeed the principal, argument in favour of the automatic rifle of less than 20 lb. weight, as against the light machine-gun of 20-40.

In sum, therefore, the light machine-gun, by reason of its greater weight and steadiness, can deliver a fire of greater accuracy and more sustained intensity than the automatic rifle, and so can perform functions for which the heavy machine-gun would otherwise have to be called in. The automatic rifle, on the other hand, possesses a greater mobility than does the light machine-gun and can for a few moments at a time develop a fire power practically as heavy. In four-fifths of a day's work in battle, then, it is as useful as, or more useful than, the light machine-gun. But the last fifth, often more important than the rest put together, it cannot undertake with much hope of success. Both have the disadvantage that they must be fed with ammunition in very difficult conditions. They must, therefore, be squad weapons and not personal weapons, and there is a tendency for the squad to group itself about the gun and so to reveal itself for what it is. Both, on the other hand, have the advantage that very few of these squads are needed, as compared with rifle-armed infantry, to attack or defend a given front.

On the whole, it seems probable that a type of the future, evolved from both, will take the form, not of the lightened machine-gun, but of the automatic rifle provided with increased magazine capacity, a cooling device, and a mount sufficiently steady, with the weight of the gun, to give a bullet grouping at short ranges as close as that of the heavy machine-gun at longer.

The rise of the light machine-gun to importance as the main weapon of the infantry battle has been followed by another development of some interest, viz. a change of principle in what may be called the personal armament of the infantry soldier. Hitherto self-sufficing, but now become a member of a gun detachment, he has felt the need of possessing some handy weapon of his own which would give him intense fire power in emergencies. The same is the case with the artilleryman and, in the present day, with many specialists such as range-takers, observers and others, who have to work in the front line but are not armed with the normal battle weapon. For these, first an increase in the capacity of the pistol magazine was tried, and later an altogether new class of weapon was designed—the machine-pistol, which is a fully automatic arm of the carbine or long pistol kind, capable of firing pistol ammunition as fast as a heavy machine-gun fires rifle calibre ammunition. Such weapons may also usefully replace the light machine-gun itself in certain conditions, e.g. bush or mountain warfare. Some examples of this new class of arm are described below.

As to whether the semi-automatic rifle—that is, the military rifle fitted with self-loading mechanism but fired by the trigger shot for shot—will become a universal infantry weapon, opinions differ. On the whole, it seems unlikely that it will do so. On the one hand, for group action the light machine-gun or perfected automatic rifle is definitely superior in accuracy, volume, and control of fire to an equivalent number of semi-automatic rifles in individual hands, whatever the discipline and team work of the individuals. On the other hand, as a personal armament for fighting at close quarters the new machine-pistol is superior in intensity of fire and at least equal in handiness. The semi-automatic rifle may develop as a weapon for sniping and skirmishing, and as the soldier's personal armament in theatres of war where the country is very open and troops are required to do a good deal of individual patrolling and stalking. Of these services, however, all except sniping can be performed by the machine-pistol; and, in sum, the semi-automatic rifle

seems likely as a military arm to become a sniper's rifle pure and simple—the military analogue of the sporting rifle, for which the semi-automatic principle is already well established.

Speculation as to the nature of the cavalry firearm of the future is now difficult, depending as it does on the tactical question of how far dispersion will be carried in the dismounted fire fight. (C. F. A.)

PRACTICAL DEVELOPMENTS

The improvement of the rifle has been confined mainly to the development of auto-loading, or semi-automatic, rifles for both military and sporting purposes, and the development of the automatic or machine-rifle for military purposes.

The semi-automatic shoulder-rifle has become an efficient and reliable weapon for sporting purposes, but no military weapon of this type has been adopted by any of the leading powers to replace the bolt-action shoulder-rifle, although some fairly successful weapons have been produced. The principal difficulty in the way of perfection of an arm of this type is the weight limitation. The present bolt-action rifles are considered by many designers to be as light as is consistent with the pressures obtained with modern powders, and the automatic action can only be obtained through additional parts, and consequently additional weight. Successful automatic rifles of 12-20 lb. weight have indeed been produced. Such rifles are somewhat less heavy than the light machine-gun, the latter being defined as an automatic, rifle-calibre weapon, with a tripod as muzzle support weighing from 20 to 30 lb. complete, and it is possible that further developments in the type may lead to its superseding the light machine-gun as above defined.

Bolt-Action Military Rifles.—It has already been noted that no important progress was made in the design of the bolt-action rifle during the World War. Quite apart from the manufacturing difficulties attending upon an alteration of model in the midst of a great crisis, and setting aside also the changes in the tactical relations of rifle, gun and machine-gun in the war, the rifles used by the various belligerents were so nearly equivalent that no one possessed any advantage over the rest which could not be compensated for by slightly better training or slightly higher moral on the other side. And not only was the invention of necessity wanting, but also the conventional type of rifle had reached a point of development beyond which it was difficult to see possibilities of radical improvement.

Substantially, then, the rifles in use at the end of the war were the same as those in use at its beginning, and this is the less surprising as many peace-time criticisms levelled at one or another model proved to be useless, or practically unimportant, in war. Thus, rifles looked upon as obsolete revealed unsuspected good qualities in the severe test of war service, and modern rifles failed to show the superiority expected. The German Mauser had been popularly credited with being the best military shoulder arm; while the British short Lee-Enfield had been severely criticized on the score of its weak body and poorly designed bolt. Yet, under service conditions, the performance of the latter was excellent; the simple action, good balance, and rapidity with which it could be worked compensating for the superior ballistic qualities of the German arm. Similarly, the French Lebel, one of the oldest service rifles (1886-93), has been looked upon as being outclassed by modern arms, it being the only military rifle with a tubular magazine; yet this rifle with the "Balle D" cartridge has greater velocity and greater striking power at ranges in excess of 800 yd. than the American Springfield, which has 360 f.s. greater initial velocity. In only one instance, apparently, did a rifle prove so unsuitable that it was withdrawn from use. The Ross rifle, the original arm of the Canadian forces, while a good sporting and target rifle, proved unsatisfactory in the mud and dirt of trench fighting.

Another factor which tended to stabilize the rifle in its existing form was the interchangeability of rifle and machine-gun ammunition. Before the war there was a distinct tendency towards reducing the calibre of the rifle and employing a lighter bullet, in order to obtain flatness of trajectory at ranges within about 800 yards. But the modern light-weight high-velocity bullet

loses its velocity very rapidly, which renders it less suitable than a heavier bullet for employment in machine-gun work, where effectiveness at long range is required. So long, therefore, as the ammunition of rifles and machine-guns remains interchangeable it is probable that no further reductions of calibre and bullet weight will take place. At the same time, the development of the heavy machine-gun itself may quite possibly call for not merely the retention of the present common calibre but an actual increase of calibre beyond what is admissible for the rifle. The principle of interchangeable ammunition has recently been questioned by some experts who would prefer that each class of weapon should be free to develop along its own lines; and already experiments have been carried out in the United States, not indeed with two calibre, but with two bullet weights, a bullet of 180 grains being designed for the machine-gun (and for occasional use for special purposes in the rifle) while the old bullet of 150 grains is retained for the shoulder weapon.

The only new model service bolt-action rifle produced by belligerents during the war on a large scale was the British rifle, .303, pattern 1914, which was later adapted to .30 U.S. ammunition and manufactured for the United States; about 2,500,000 rifles of this type being produced in that country during the eighteen months preceding the Armistice.

British Rifles of the War Period.—Before the war, the British service rifle, the short Lee-Enfield of .303-in. calibre, had been subjected to a good deal of criticism, and the War Office, after much experimenting with various types of cartridges, found that it was not possible to obtain as high a velocity with this rifle as was desired. An improvement was effected, however, in the adoption of the Mark VII. ammunition, the pointed bullet of which weighs 174 grains instead of 215 grains as in the Mark VI., the muzzle velocity being 2,440 f.s., with a chamber pressure of 45,000 lb. This ammunition, however, did not give the ballistic qualities desired and the design of a new rifle was taken up. A rifle was finally evolved with a bore .276 in. in diameter, and chambered for a rimless cartridge, giving a muzzle velocity of about 2,800 f.s., and a chamber pressure of 51,000 lb., and it is probable that this model would have been further perfected and adopted but for the beginning of the war. Military considerations then prevented its adoption in its original form, and it was modified to take the existing Mark VII. .303 ammunition, and manufactured in the United States as the "British Rifle, Pattern 1914." The short magazine Lee-Enfield with Mark VII. ammunition, however, remained the standard British arm throughout the war; though the new rifle was also used.

Upon the entrance of the United States into the conflict, as a number of American factories were equipped to manufacture this rifle, it was again modified to accommodate the U.S. service ammunition and used as a substitute for the calibre .30, model of 1903 (Springfield), under the name of the "U.S. Rifle Model of 1917." As chambered and bored for the U.S. ammunition, the rifle had approximately the same ballistic qualities as the Springfield. The British and American models of this rifle are the same in their essential features, except that the latter has not the long-range (dial and aperture) sights of British rifles. A remarkable feature common to both rifles is the position of the rear sight between two protecting lugs on the bridge of the receiver. This position of the rear sight gives a distance from back sight and fore sight of 31.76 in., that is, almost exactly over the trigger instead of in the customary position, a hand's breadth or more in front of the magazine. Further details will be found in the article SIGHTS. The length of the rifle overall is 46.3 inches. The weight without bayonet is 9 lb., 3 oz.; the sword bayonet is about 22 in. long (blade 17 in.) and weighs 15 oz. The magazine holds five cartridges which are loaded from a clip. The bore has five grooves, left-hand uniform twist, one turn in 10 inches.

The action of this rifle is as follows (figs. 1 and 2). The cycle of operations is assumed to start with the extraction of a fired cartridge case. The bolt handle is raised and the cocking piece forced to the rear in the bolt by the half-cocking cam. This also withdraws the striker into the bolt. When the locking lugs on the bolt are clear the extracting cam on the bolt and receiver engage and the continued

rotation of the bolt retracts the latter and loosens and partly withdraws the cartridge case (primary extraction), the extractor and sleeve being prevented from turning by the receiver. When the limit of the turning movement in the bolt is reached, it is drawn to the rear, withdrawing the empty cartridge case; during this movement the cocking piece rides over the sear nose and depresses it; the safety stud rises in the clearance cut in the bolt. When the cocking piece clears the sear nose, the sear spring returns the sear to normal position. The slotted locking lug (left hand) of the bolt now reaches the ejector, the latter protruding in the slot sufficiently to strike the rear of the empty case and eject it to the right. After a further slight backward movement the bolt lug comes in contact with the bolt stop, preventing further movement. If the magazine is now empty the follower rises and its rib prevents the closing of the bolt. If not, the magazine spring has pushed another cartridge up and into the path of the bolt, the forward movement of which forces it forward and up over the cartridge ramp.

During the early part of the closing movement of the bolt, the ejector is pushed outward by the bolt. Later, the sear notch in the cocking piece engages the sear nose, and is arrested. The bolt then slides forward over the striker, further compressing the main spring.

When the rotation of the bolt by the handle begins, the locking lugs engage the locking cams, and force the bolt home, seating the cartridge, and further compressing the main spring. The rotation of the bolt restores the half-cocking cam, so that it is out of the path of fall of the cocking-piece lug.

The bolt is now locked, the mainspring is fully compressed, and the cocking piece is held by the sear nose.

When the trigger is squeezed, the bearing of the trigger first acts on the bearing of the receiver, slowly depressing the sear nose. Then the heel of the trigger engages the receiver, and completes the depression of the sear nose, which ends in the release of the cocking piece by the sear nose. The striker is then acted upon by the mainspring, and, striking the primer of the cartridge, detonates the same.

FIGS. 1 and 2.—British Rifle (Pattern '14) U.S. Model of 1917.

During the depression of the sear nose, the safety stud rises through the hole in the bottom of the well and enters the interlock slot in the bolt. If the bolt is not fully locked, the interlock slot will not register with the safety stud, and the trigger cannot be pulled.

United States.—When the United States entered the war its standard rifle was the "U.S. Rifle, Model of 1903" (Springfield). There were only about 600,000 of these on hand, and very limited possibilities of immediate expansion. To obviate delay, therefore, it was decided, as above mentioned, to adopt the British Pattern '14 rifle which had been manufactured in the United States in large quantities. This rifle, modified as previously noted, was used very successfully by a large portion of the U.S. troops; only the regular army and part of the National Guard continuing to use the Springfield. The Springfield, however, is still (1921) the official arm, the 1917 rifles having been withdrawn after the Armistice.

Other Nations.—The Lebel magazine rifle, calibre 8 mm., model of 1886-93, is still the standard arm of the French infantry. The magazine is tubular, lies under the barrel, and holds eight cartridges which are loaded singly. The carbine, model of 1890, and the rifle, model of 1907-15, were also used to a considerable extent. These are magazine rifles, having a one-piece stock and a bolt with a turning head. They are loaded with a charger containing three cartridges. A box magazine was later designed for these rifles, increasing the capacity to five cartridges. Several

other types were used by the French, many of the old single-loading "Gras" rifles of the 1874 model being adapted.¹

Mausers rifles in different calibres were used by *Germany, Turkey, China, Portugal, Serbia and Brasil.*² The Japanese "Arisaka," or "38th Year," also has a Mauser action. Many of these rifles were purchased from Japan by Russia early in the World War and also by Great Britain for training purposes. It was reported that since the Armistice Japan has increased the calibre both in new rifles and in the existing stock from 6.5 mm. (256) to 7 mm., the reason given for the change being that the 6.5-mm. bullet is too small to develop sufficient wounding power. This calibre is used by several other nations and is the smallest used in military rifles. The change is interesting, since the tendency had been towards reduction of calibre.

The standard arm of the Russian infantry is the "Three line" magazine rifle, 7.62-mm. (.3-in.) calibre. A new type of ammunition has been adopted for this rifle, having a pointed bullet weighing 148 grains and giving 2,820 f.s. velocity with 50,000 lb. pressure. The Russian Government also bought large quantities of Winchester, model of 1895, magazine rifles of the same calibre, the only lever-action magazine-rifle used in the war.

Austria-Hungary used the 8-mm. Mannlicher, "Straight Pull" rifle, model 1895, and carbine. Mannlicher type rifles were also used by *Italy, Bulgaria, Rumania and Greece.* The *Belgians* used the magazine rifle, calibre 7.65 mm., model of 1880, which has a Mauser action. The latest ammunition for this rifle has a pointed bullet weighing 154 grains with a velocity of about 2,740 f.s. The *Swiss* Schmidt-Rubin rifle has been redesigned to chamber a new rimless cartridge having a 170-grain streamline bullet with a velocity of 2,660 f.s.

SPECIAL BOLT-ACTION RIFLES

Snipers' Rifles.—Several types of rifles have been developed by the various Powers for the use of "snipers," whose function it is to pick off with single shots individual scouts, officers, men of working parties, enemy snipers, etc. Snipers work as a rule in pairs wherever feasible, one acting as an observer, the other as a rifleman. The rifle used for this purpose is usually a very carefully selected specimen of the standard service rifle, fitted with telescopic sights of low power, or some other variety of optical sights, though plain sights are sometimes used. The British snipers used the short Lee-Enfield rifle with various forms of telescopic and other optical sights, and also the 1914 rifle with a special hack sight. The U. S. rifle is fitted with a Warner and Swasey telescopic sight, 6-power, 41° field, which is attached to the standard rifle by side brackets, but this combination is not entirely satisfactory and a new telescope and method of mounting are being developed. The German sniper's rifle was the standard Mauser with brackets fastened by screws to the top of the magazine to take a *Goetz, Luxor, or Zeiss* telescope, generally of 24 or 3 power. The mounting of the telescope over the bolt and magazine makes it necessary to use the rifle as a single-loader and prevents the use of the regular sights while the telescope is attached. This method is, however, preferred by riflemen as aim may be taken with the cheek against the stock in the usual manner; the superior accuracy obtained offsetting these disadvantages. In the German sniper's rifle the telescope can be very quickly removed from its brackets and the rifle used the ordinary way.

¹ The German infantry throughout the war carried the 1898 pattern Mauser (7.9 mm.). The cavalry carbine of the same pattern and calibre was also occasionally used by infantry as well as by cavalry serving dismounted in the trenches, and by the personnel of light machine-gun squads. During the trench-warfare period of the war, spare magazines holding 25 cartridges were designed for attachment to the underside of the ordinary magazine, in order to obtain an increased volume of fire for emergencies; these were, however, clumsy and unpopular with the troops, and were not generally used. The only important modification of the standard arm was the introduction in summer 1915 of a short rifle (43.5 in.) known as the Erfurt rifle. This has the same trench action, calibre, and magazine as the 1888 rifle, and, apart from the reduced length, differs from it only in having the sliding parts of the breech covered by a dustproof metal casing, the barrel cased in wood (as in the British and other short rifles) and the muzzle fitted with a flash-reducing attachment. The bolt-handle is curved down close to the stock. This weapon was only issued for service in the last months of the war, but seems to have been retained as a standard weapon in the post-war army and police. Troops of older categories employed in garrison and line of communication duties had the old magazine rifle of 1888 (7.9-mm. calibre).

² The new Brazilian 7-mm. ammunition has the highest muzzle-velocity of any military small-arms ammunition, although several of the new cartridges closely approach it.

Periscopic Rifle Holders or "Sniperscopes" have been designed and used with some success, although it cannot be said that these devices were ever popular or capable of very accurate or rapid fire. The tendency when using them is to shoot high and they are only reasonably accurate at ranges up to 500 yards. In the instrument developed by the Munition Invention Department of the British Government (fig. 3) the periscope (aa) and shoulder piece (c) are rigidly combined with each other and with a shoe (d) which takes the butt of the rifle. A trigger on the shoulder piece is connected to the rifle trigger by a cord (eee). Pivoted to the right side of the shoe is a system of levers (bbb) which enables the firer to open and close the bolt by means of a handle close to his right hand. The periscope itself is a simple mirror-periscope.

FIG. 3.—Periscopic Rifle Holder (British Type).

Anti-tank Rifle.—The German anti-tank rifle (fig. 4) is a single-shot calibre 13-mm. Mauser action rifle brought out as an emergency weapon and intended to serve as a stop-gap pending the construction of a 13-mm. machine-gun. The weapon is intended for short-range work only, as the sights are graduated to only 500 metres. It is very heavy (37 lb.) and has a total length of nearly 66 in., the barrel being 39 in. long. It is provided with a bipod. The bullet, which weighs 801 grains, is pointed and armour-piercing, has an initial velocity of about 2,450 f.s., and a penetration of 20 millimetres in the best steel is claimed at a range of 500 yards. It is, however, very heavy for a portable arm, and, being a single-shot weapon, it has a very slow rate of fire. On account of the heating of the barrel and the heavy recoil, the fire cannot be sustained for more than 20 shots at a time. Each rifle was served by two men, carrying 124 cartridges as well as the rifle and accessories and their personal armament. The rifles were used in squads of three rifles, or singly, or in co-operation with heavy machine-guns using armour-piercing bullets, according to circumstances. The Germans had a high regard for this weapon.

FIG. 4.—German Anti-Tank Rifle.

High-power Rifles.—Sporting rifles with an initial velocity of 3,000 f.s., or slightly more, are now in use. These rifles have no particular feature except the additional strength necessary to withstand high pressures. The so-called "explosive" effect of high-velocity bullets upon striking make them extremely effective for sporting purposes.

SEMI-AUTOMATIC RIFLES

As already mentioned, efforts are being made to produce a semi-automatic shoulder-rifle to replace the bolt-action rifle. The successful sporting weapons of this type which have been devised are not considered suitable for military use, as the powder pressures and velocities obtained from their cartridges are much below those obtained with military ammunition. Sporting rifles are not subjected to the severe conditions that are usually encountered by the military

³ The order for a design was given in Dec. 1917 and in spite of the manufacturing difficulties which naturally presented themselves with an arm of such unusual proportions, the Mauser works were able to begin quantity supply in April 1918 (*Schwarte, Technik im Weltkriege*, p. 21). (C. F. A.)

arm; the sportsman seldom fires more than three or four shots in quick succession and is usually in a position to give the self-loading rifle the care which its more complicated mechanism requires.

The principal requirements in a semi-automatic rifle are that the rifle shall not weigh more than nine or ten pounds, and shall have a simple mechanism which will stand the shock of service ammunition and the wear and tear of campaigning. The weapon must be capable of being used either automatically or by hand as an ordinary rifle, and for the rest must possess all the qualities now demanded of a good bolt-action rifle. The automatic action, therefore, is not considered a substitute for any of the qualities of the present shoulder-rifle. No semi-automatic weapon so far designed has fulfilled these conditions to such a degree that it has been adopted in place of the bolt-action rifle. The Mondragon, a Mexican invention, has, however, been used by the Mexican Government to some extent, and in a modified form. A modification of this weapon was also used by Germany in the war, notably for the armament of aeroplanes. Two French models, the St. Étienne and the "Carabine Meunier," were brought out toward the close of the war, but not extensively used.

FIG. 5.—Winchester Auto-Loading Rifle.

The U.S. Ordnance Department recently (1920) held competitive tests, and further developments and tests have been made.

The principal advantages expected from the semi-automatic rifles are: increased rapidity of fire, less physical labour on the part of the soldier, and better *moral*, due to the knowledge that he can devote all his attention to the enemy and shoot without exertion or haste when necessary. On the other hand, the desirability of the semi-automatic rifle is not universally conceded. Some authorities consider the rate of fire of the present rifle to be quite as high as is consistent with accurate shooting and lay stress on the difficulties of ammunition supply.¹

Semi-automatic Sporting Rifles.—The Winchester auto-loading system for rifles (fig. 5) utilizes the inertia of a heavily weighted bolt working against the compression of a coiled spring in the fore end to delay the rearward motion of the bolt at the moment of firing until the bullet has left the barrel. After this inertia is overcome, there still remains enough force to the recoil to move the bolt to the rear, eject the empty cartridge case, cock the hammer against the compression of the hammer spring, and finish the compression of the bolt

FIG. 6.—Browning Auto-Loading Rifle.

spring. When this has been accomplished, the bolt moves forward actuated by the bolt spring and feeds another cartridge into the chamber. A pull of the trigger now fires another shot. This rifle is made in various calibres, the most powerful being .401 in. The 200-grain bullet in this size gives a muzzle-velocity of 2,132 f.s. and has a muzzle-energy of 2,020 foot pounds. The French Air Service used this type of rifle to a limited extent in the armament of aeroplanes.

The Browning auto-loading system (fig. 6), used by Remington (U.S.A.) and the Fabrique Nationale (Belgium), differs from the Winchester in that the barrel (1), breech bolt (2), and bolt carrier (3) are locked together at the moment of firing, these parts recoiling together against a powerful spring (7) in a casing surrounding the barrel and in which the barrel slides. The rearward motion pushes the hammer (4) backward, cocking the action and compressing the

¹ The incorporation of the light machine-gun in the small fighting unit of infantry bears on this question. (C. F. A.)

action spring (5) through the link (6) and the recoil spring (7). A buffer spring (8) also serves to retard the recoiling parts. At the completion of the backward motion the bolt-carrier latch (9) springs into a notch (10), locking the bolt in its rearmost position. The barrel and bolt carrier now start forward actuated by the recoil spring around the barrel; the bolt carrier after moving a short distance is held by the bolt-carrier latch; the barrel continues its forward movement, turning the bolt by means of a helical cam slot in its side and unlocking it. The empty cartridge case is held until the forward motion of the barrel withdraws it from the chamber, after which it is ejected. When the barrel has reached its forward position, the barrel extension (11) has forced the barrel lock down. This reacts against the bolt-carrier latch and allows the bolt carrier to be pushed forward by the action spring (5), carrying a fresh cartridge from the magazine (12) into the chamber and rotating the bolt so that the locking lugs are forced into their seats in the barrel extension, thus locking the bolt to the barrel.

FIG. 7.—Mondragon Semi-Auto Rifle.

This rifle is made in .25-in., .30-in., .32-in., and .35-in. calibres. In the last-named the 200-grain bullet has a muzzle-velocity of 2,020 f.s. and an energy of 1,776 lb. The magazine is loaded with a clip of five cartridges similar to military rifles. Owing to the locked bolt and recoiling barrel, high pressures can be used in this arm. The cartridge is reduced in diameter or necked down for the bullet. The mechanism is, however, much more complicated than in a rifle where the breech only is blown back.

Semi-automatic Military Rifles.—The Mondragon semi-automatic military rifle (fig. 7) is the invention of Gen. Mondragon of the Mexican army. It was invented about 1891 and developed to its present state by Germany about 1915. The rifle is gas-operated, the gas being taken from a port in the barrel. It weighs about nine pounds, has the general appearance of the ordinary service rifle, is fitted for a bayonet, and is made in 7-mm. calibre. The characteristic feature of this rifle is the bolt mechanism, which permits the rifle to be used either as an auto-loading weapon or as a hand-operated shoulder rifle. The bolt (1) has three locking lugs on the forward end of the bolt and four on the rear end of the bolt, which are locked into locking recesses of the receiver (2). The bolt is made to rotate by two helical cam slots (3) in the side; two cam lugs, which are carried by the bolt handle, work these slots. The bolt handle is connected with the gas piston so that when the powder gases enter the gas chamber and drive the piston to the rear, the bolt handle is carried with it and causes the bolt to rotate and unlock, and move to the rear, extracts the empty case and compresses the recoil spring (4) which is coiled round the gas cylinder, and drives the mechanism forward after it has been arrested in the rear by the buffer spring. A gas adjustment is provided to regulate the amount of gas delivered to the gas cylinder, so that the rate of working can be to some extent regulated. The magazine has a capacity of 10 rounds. Another form of magazine, for aircraft purposes, is of the Luger "snail," or barrel type (see PISTOL), and holds 30 rounds. The rifle is provided with a separate hammer (5) which is linked up with the trigger mechanism as

FIG. 8.—St. Étienne Semi-Auto Rifle.

shown in the section. The change to hand-loading is done by means of a releasing catch on the bolt handle which disconnects this from the gas piston. The gas port in the barrel may also be closed by means of a valve. A safety device (6) is provided which disconnects the trigger if carried in a safe position.

The German pattern was officially known as the Aviator's Auto-matic Carbine (*Flieger-Selbstlader Karabine*), model 1915, and was chiefly and successfully used for the purpose indicated by its name. It was also for a time tried as an artillery carbine, but for this purpose it proved unsuitable, in that it failed to stand the rough usage and careless handling of field warfare.

The St. Étienne Semi-automatic Rifle (a French "semi-automatic rifle, model 1918") is a gas-operated semi-automatic rifle which weighs about 11½ lb., is about 32 in. long, and has an ordinary rifle sight and bayonet fitting (fig. 8). It takes the French Lebel 8-mm. cartridge. The magazine which has a capacity of five cartridges is charged through the bottom of the magazine housing (8), which is hinged.

When the bolt handle, which is attached to the bolt (9), is pulled to the rear, the hammer (10) is forced to the rear against the action of the hammer and sear spring (11) until the sear (12) is engaged in the sear notch in the trigger (13). The rearward motion of the bolt compresses the recoil spring (15) which, when the bolt handle is released at the rear position goes forward and drives the next cartridge into the chamber, while the hammer is held in the rear position by the sear and trigger ready for firing. The trigger is pulled and released for each shot, but extraction and ejection of the fired cartridge case and the feeding of the new cartridge are automatic. When the trigger is pulled, the sear is released and allows the hammer to go forward and strike the firing pin which ignites the cartridge. When the cartridge is ignited a portion of the powder gases pass through the gas port (16) into the gas cylinder (17) which drives the gas piston to the rear. The gas piston is linked with the bolt mechanism through a slide which transmits the force of the gases to the bolt. This serves to unlock the bolt and drive it to the rear to extract and eject the empty case and to compress the action spring and cock the hammer for the next shot. The bolt body is forced to the rear by the slide which is attached to the gas piston, and also linked with the bolt head (18) through rotating cams which rotate the bolt head sufficiently to clear the bolt head locking lugs of the locking recesses in the receiver.

AUTOMATIC RIFLES AND LIGHT MACHINE-GUNS

As has been stated in an earlier part of this article the development of new tactical methods and conditions in the World War soon produced a demand for a light machine-gun or automatic rifle which could keep up with, and participate in, an

FIG. 9.—Browning Automatic Rifle.

infantry attack at every stage of its progress. Various types of weapons were adopted for this purpose and classified as light machine-guns or automatic rifles. There is no distinct separation of these types, the term "light machine-gun" being usually applied to machine-guns weighing 20 to 30 lb. fired from a bipod and used for fairly sustained direct fire. Practically all types are air-cooled by means of a heavy barrel with annular rings or a radiator. The automatic rifle, while it is sometimes supplied with a bipod, may be fired from the hip or shoulder and

The rifle is light and portable, weighing only 15½ lb. and being only an inch or two longer than the short military rifle. It can be handled by one man as a shoulder rifle. As it is heavier than the ordinary military rifle, the recoil is very slight, and a man can fire the gun continuously without distress.

By means of a change lever, the action of the gun is made either semi-automatic (the trigger being pulled for each shot), or automatic (being continuous as long as the trigger is kept pressed and cartridges are supplied).

As a semi-automatic rifle it is very effective. As the trigger pull is as light as that of an ordinary military rifle, it is possible with practice, to fire 100 shots a minute without unduly tiring the finger. Used in this manner every shot can be well directed, which makes the gun in some conditions as effective as the heavy machine-gun, with a considerable saving in the amount of ammunition expended.

The gun, firing automatically, has a rate of between 450 and 500 shots per minute. The speed can be regulated to a certain extent by adjustment of the gas regulator. The weapon can be used as freely when firing automatically as when firing single shots, the firer lying down, standing, or advancing at will.

When a magazine has been emptied it can be dropped out of the gun by pressing the magazine release in the trigger guard and a full magazine quickly pushed into place with one hand, so that very little time is lost in changing magazines.¹

The mechanism is very simple and also extremely durable. Tests have been made where over 50,000 rounds have been fired out of the same rifle without any of the parts showing distress.

The rifle is gas-operated. A portion of the powder gases, while under pressure, are trapped near the muzzle of the gun and are caused to act upon a gas piston. The pressure of the gases forces the piston and slide to the rear against the action of the recoil spring, until stopped by the buffer, when the recoil spring returns the mechanism to its forward position.

The receiver (21) in which the barrel is firmly screwed contains the principal mechanism of the gun. The bolt-supports (23), upon which the bolt slides, are riveted in position. The bolt guide (25) fits in a slot cut in the receiver wall and is held in position by the bolt guide spring. The change lever stop (26) projects from a hole in the receiver wall in the path of the change lever and must be depressed before the change lever can be moved to the safe position. The buffer tube (28) behind the receiver contains an arrangement of friction cones, cups and springs. On the left-hand side of the receiver

FIG. 10.—Browning Automatic Rifle.

is capable of delivering limited sustained fire. Its weight varies from 14 to 20 pounds. The German "08/15" and "08/18" and the Bergmann, Lewis and Benet-Mercie are generally spoken of as light machine-guns. The Browning, Chauchat, light Hotchkiss and Madsen are examples of automatic rifles.

The *Browning Automatic Rifle* (figs. 9 and 10) is the standard automatic rifle of the United States army.¹

¹ Brought out in 1917, just after America entered the war, and available in small numbers by Feb. 1918, it was not employed in battle till Sept., Gen. Pershing having become so convinced of its superiority over all other types in use that he preferred not to expose it to capture and copying by the enemy till the American army had been supplied with it on a large scale and had reaped the fruits of its superiority in a great battle. In effect, none was used before his offensive battles of Sept. but 4,608 were in action between that date and the Armistice. (C. F. A.)

are grooves in which the operating handle (34) slides. The forward end of the gas cylinder tube (36) is rigidly connected with the barrel.

The bolt (39) carries the extractor (40) which is held by the extractor spring (41). The firing pin (42) fits in the bolt, and has a cam lug which engages with a corresponding cam surface on the bolt lock (43). The downward motion of the bolt lock forces the firing pin back and prevents it from touching the cap of the cartridge until the arm is ready to fire. The bolt lock and link (44) are pivoted to the rear end of the bolt. The link connects the bolt lock and the slide (45), which moves horizontally in grooves in the receiver, the gas piston (46) being permanently attached to it. The slide is slotted to permit the magazine to pass through it, and has a notch on its lower rear end to engage with the sear (47). The link pin (48) passes through the link, hammer (49), and slide, pinning the three parts

² Magazines holding 20 cartridges are the standard size; they are also made to hold 30 and 40 cartridges. They are themselves filled by a device which presses in the cartridges, five at a time, from the usual clips.

together in such a manner that the link may swing on the pin as a pivot. The link pin also protrudes through a slot in the receiver to engage the operating handle. The recoil spring (55) is encased in the gas piston, its front end pushing forward on the piston while its rear end rests against the head of the recoil spring guide.

The sear (47) is pivoted in the sear carrier (51) by the sear pin which also holds the sear carrier to the trigger guard (52). The holes through which the sear pin passes in the trigger guard are slotted, allowing a slight horizontal movement of the sear carrier. When the sear engages in the notch of the moving slide, the counter recoil spring (53) acts as a buffer, allowing the sear carrier and sear to move instead of suddenly stopping the movement of the slide.

The ejector (54) is a flat spring which yields slightly when struck by the empty cartridge case so that the latter is gradually ejected.

Action of the Mechanism.—With the gun in the ready-to-feed position and the change lever set for semi-automatic fire the cycle of operation when the trigger is pulled is as follows:—The connector which is pivoted in the trigger moves the sear (47) out of engagement with the notch in the slide and is cammed forward allowing the sear to spring into position to engage the slide on its return. The recoil spring (55) which has been compressed during the recoil of the mechanism, drives the piston (46) and slide (45), carrying the bolt (39), bolt lock (43), link (44) and hammer (49) forward. As they move forward the lower edge of the bolt strikes the upper edge of the top cartridge in the magazine and drives it forward into the chamber.

As the parts are nearing their forward position, the rear of the bolt lock (43) which curves downward, comes in contact with the rounded end of the bolt-supports (23) and the rear end of the bolt lock is started moving upward. As the slide moves further forward, the top end of the link, which is pivoted to the bolt lock, tends to move upwards as the lower end is swung forward with the slide, and the link forces the rear end of the bolt lock in front of the recoil shoulder in the receiver, thus positively locking the breech, as shown in the illustration. The motion of the bolt as the bolt lock swings upward, is gradually stopped so that the bolt is not stopped suddenly, but very gently as its forward horizontal motion is transformed into the vertical motion of the rear of the bolt lock.

The hammer strikes the firing pin and the cartridge is ignited. The forward shoulders of the slide then strike the heavy buttment of the gas-cylinder tube, and the motion is arrested.

After the bullet passes the gas port in the barrel near its muzzle, the expanding gases enter the gas cylinder and drive the piston and slide rearward. The rear of the bolt lock is brought down away from the recoil shoulder of the receiver, and is started back, gradually starting the bolt rearward with it, but by the time the bolt starts to move, the pressure of the gases has subsided, so that the empty cartridge is no longer expanded against the walls of the chamber, but comes out freely. Extraction troubles are thus avoided. The bolt is both stopped and started gradually and is not damaged with hammer-like blows. The empty case is drawn from the chamber by the extractor until its under edge strikes the ejector, when it is ejected to the right and forward; this avoids interference with a man immediately to the gunner's right.

The recoiling parts are arrested when the slide strikes the buffer, and the sear once more engages in the sear notch, which holds the slide and bolt mechanism to the rear with the breech open.

FIG. 11.—Chauchat Machine-rifle.

Chauchat Machine-rifle.—The Chauchat machine-rifle, model of 1915 (fig. 11), also known as Rifle C.S.R.G., was designed by a commission presided over by Col. Chauchat. It weighs about 19 lb. and is about 45 in. long. It takes the 8-mm. Lebel cartridge or, in the case of the guns taken over by the U.S. army, the U.S. model of 1906 ammunition.

This rifle is recoil-operated; the recoil being assisted by deflecting part of the gases as they escape. The cooling of the barrel is assisted

¹ As already mentioned, the Browning gun was reserved until a large supply could be put into line at one time. Pending this, the American forces in France were equipped with the Chauchat of which some 34,000 were adapted to U.S. ammunition.

by an aluminum radiator with annular corrugations surrounding the barrel. The backward and forward motion of the barrel causes air to be driven into the holes in the radiator casing (cf. the Lewis gun, fig. 14) which also assists in the cooling. The locking of the bolt mechanism is positive and is done by two locking lugs on the bolt head which are rotated into locking recesses of the breech casing. Lugs are provided to guide the bolt head and bring it in contact with the cam cuts in the bolt body. The cartridges are fed from a semi-circular magazine holding 20 cartridges, when rim cartridges are used, and from a straight magazine when rimless cartridges are used. A regulator is provided, which adjusts the gun for safety, for automatic fire, or for semi-automatic fire.

The action of the mechanism is divided into two phases: the forward motion and the backward motion. The rifle is loaded by pulling the operating handle to the rear until the mechanism is arrested by the sear (57). A charged magazine is inserted into the magazine opening in the gun, the magazine being held in place by the magazine catch (58). When the trigger is pulled it causes the trigger bar (59) to rotate the hand sear (60) against the under side of the breech casing (61). This forces the sear lever (62) downward, depressing the sear and releasing it from the notch of the feed piece.

The bolt head (63), bolt body (64), firing pin, and feed piece move forward under the action of the mainspring, which is encased in the spring tube. The feed piece strikes the upper part of the head of the cartridge in the magazine and forces it forward out of the magazine. At this time the cartridge guide (65) is being held up by the roller working in the cartridge guide cam slot. The bullet is directed into the chamber, the magazine spring forcing the rear end of the cartridge up into the path of the bolt head just as the cartridge is freed from the lips of the magazine.

The cartridge guide cam causes the cartridge guide to drop, thus letting the feed piece pass forward and release the barrel catch (66).

The bolt-head stop (67) keeps the bolt head and bolt body at their extended positions so that the locking lugs in the bolt head are vertical, thereby permitting their entrance into the locking recesses. The bolt-head stop then comes out of the breech casing, the bolt head is released and rotates so that the locking lugs engage in the locking recesses in the breech casing to lock the mechanism. The bolt body and firing pin continue to move forward, and the extractor grips the rim of the cartridge as the bolt head turns. The firing pin primes the cartridge just as the feed piece releases the barrel catch.

Backward motion: The recoil from the explosion combined with the action of the gases on the barrel nut (68) carry the breech mechanism and casing in a locked position to the rear against the action of the recoil spring (69) and mainspring. The breech casing and barrel (70) being free to move, immediately start forward. The breech mechanism is held back, due to the sear engaging in the sear notch on the tail of the feed piece. As the barrel moves forward the empty cartridge case is drawn from the chamber by the extractor. As the barrel continues its forward motion the front end of the empty case clears the opening in the breech housing and it is thrown out through the ejection-opening by the pressure of the ejector upon its base. If the regulator is set for single fire the hand sear is immediately released by the trigger bar. This allows the sear to lock back the breech mechanism until the trigger is again pulled. If the regulator is set for automatic fire the hand sear is not released, but is held up

by the trigger mechanism. The rear cam surface on the bottom of the breech casing strikes and depresses the hand sear just as the barrel reaches its forward position. The hand sear forces the sear lever down, which in turn depresses the sear, releasing it from the sear notch of the feed piece. This allows the breech mechanism to go forward and repeat the cycle.

This rifle is provided with a forward grip (71) for use in marching fire. A bipod (72) is provided for prone or fixed position firing.

Hotchkiss Light Machine-Rifle (fig. 12) weighs 18½ lb., is air-cooled and gas-operated, magazine-fed, and provided with a bipod (73), a hand grip (74) and a shoulder stock. The general mechanism is the same as in the Hotchkiss machine-gun. The speed regulator and buffer mechanism is especially interesting.

The regulation of the speed of the gun is controlled by an escapement mechanism, located in the tube (75), which arrests the recoil mechanism and releases it after the catch has been set free of escapement.

This weapon, like the German light machine-guns described later, and unlike those hitherto dealt with, is derived directly from the heavy machine-gun. It is the outcome, therefore, of an effort to increase the mobility of the machine-gun rather than an attempt to improve the fire power of the shoulder rifle. As a true automatic rifle was available in the form of the Chauchat, and as all facilities for the manufacture of typical machine-gun elements were absorbed by the demand for heavy machine-guns, this type was not manufactured on a service scale during the war. It is however interesting as an instance of the machine-gun approximating to the machine-rifle.

FIG. 12.—Hotchkiss Machine-Rifle (French).

Madsen Machine-Rifle (fig. 13) is a recoil-operated, air-cooled rifle weighing about 16 pounds. It may be fired either semi-automatically or automatically. The rate of fire when used as an automatic is about 500 shots per minute. The barrel is about 23 in. long, somewhat larger in diameter than the barrel of the ordinary shoulder rifle, and is provided with annular rings and a perforated barrel casing to facilitate cooling. A bipod and a rest attached to the butt steady the rifle when used by a firer lying down. The cartridges are fed from a detachable quadrant-shaped, 40-round magazine projecting above the gun. A detachable barrel is provided for the purpose of gaining a more sustained fire, the system being to replace the barrel, when it has been excessively heated, by another barrel, and continue the fire while the first barrel is being cooled. It is claimed that the barrel may be changed in from 12 to 20 seconds.

FIG. 13.—Madsen Machine-Rifle (Russian).

The action of the mechanism is as follows:—

When the gun is loaded, as shown in the figure, and the trigger (76) is pulled, the hammer (77) under the force of the hammer spring (78) strikes the link (79), which transmits the blow to the firing pin and so to the cap. On firing, the barrel (80) and bolt mechanism (81), locked as a unit, recoils, compressing the recoil spring (82) until the link disconnects the bolt from the barrel lock and allows the bolt to recoil sufficiently to cock the hammer, extract and eject the fired cartridge case. The accelerator (83) assists in driving the bolt to the rear as it engages on the accelerator lug (84) during the recoil and transmits the momentum of the barrel and mechanism to the bolt. The accelerator also drives the barrel home during the forward stroke of the bolt.

A safety device (85) controls the trigger. A change lever (86) enables the gun to be fired semi-automatically or automatically.

The Madsen light machine-rifle was designed some years before the war, and for a time all Russian cavalry divisions had automatic rifle sections armed with it. These were abolished before the outbreak of the World War and replaced by ordinary machine-gun sections as the lighter weapon was found to be too delicate for the field. The Madsen was, however, again taken into use by the Russians during the war, and under the name of the "Musket" it formed the armament of the German "Musket battalions" which were created in 1915. Some of these units with their guns were engaged in the battle of the Somme 1916 but apparently the result, in the trying

conditions of the trench-warfare battle, was not very successful.¹ Tests have been made of the Madsen gun at different times in the British and United States armies.

The *Lewis Machine-Gun* (fig. 14) is a magazine-fed, gas-operated, and air-cooled machine-gun. The ground type, which is used as a light machine-gun, weighs 26½ lb., and is capable of firing at the rate of about 600 shots per minute. The ammunition is fed from a drum-type magazine placed over the receiver, and which holds 47 rounds for ground use, or 97 rounds for aircraft use. It was invented by Col. I. N. Lewis of the U.S. army shortly before the outbreak of the World War, and large numbers were purchased by the British Government to supplement the available Vickers (heavy) machine-guns. When the differentiation of light and heavy types began, therefore, the British army found itself already provided with a gun of what was judged to be sufficient mobility, handiness and firepower, and the Lewis gun became and remained the standard type of the light machine-gun for the fighting unit of infantry. In the United States, on the other hand, the military authorities determined to adopt the still lighter Browning, and pending the supply of this, the Chauchat as above mentioned. The Lewis gun, thus classed among the heavy machine-guns, was, however, used in large numbers for aircraft, and a few were employed for training purposes as well, some 30,000 of U.S. rifle calibre being ordered and produced. For aircraft, the gun was used by the French also, while in 1918 the Germans, who had a high opinion of it, armed some newly formed motor-cyclist units with captured weapons.

The principal feature is the cooling system, which consists of an aluminum radiator having deep longitudinal fins surrounded by a thin tubular casing which projects several inches beyond the barrel and is reduced in diameter at the front end. These parts with the barrel mouthpiece constitute the cooling system. The mouthpiece deflects the powder gases against the interior wall of the forward portion of the radiator casing in such a manner as to draw a current of cool air through the open rear end of the casing and along the thin fins from which it absorbs the heat. The heat conductivity and low specific gravity of aluminum combined with the construction described produce a light-weight cooling mechanism. The Lewis machine-gun is provided with a bipod mount. The over-all length is approximately 51 inches. The muzzle velocity and chamber pressure are approximately the same with a given ammunition as that of the shoulder rifles in which the ammunition is used.

Action: To operate the Lewis machine-gun, a loaded magazine (10-11) is placed in position on top of the gun, and the charging handle (8-4) is pulled to the rear until the rear nose (5-8) engages in the rear notch in the rack (8-1). The gun is then ready to be fired. When the trigger is pulled and held, the rack and piston (8-6) move forward under the action of the mainspring (9-9), which in unwinding rotates its gearwheel (9-7) and rack to carry the bolt (4-4) forward. As the operating rod moves forward, the front top edge of the bolt strikes the lower edge of the cartridge which is held in the magazine and feed-way, and drives the cartridge forward into the chamber. The locking lugs on the rear of the bolt move clear of the guide slots in the receiver so that the bolt is free to rotate. The locking of the bolt is then accomplished by the striker post coming in contact with the left side of a cam slot in the bolt, which forces the bolt and its lugs to turn one-eighth of a turn to the right. The extractor springs over the rim of the cartridge case (or the cannelure if rimless) as the bolt forces the cartridge in the chamber. The magazine is held by the rebound pawl (6-8) during the forward move of the bolt and piston. The feed operating arm (7-5) acted upon by the feed operating stud (4-1) on the rear of the bolt, returns to its normal position during the forward motion of the bolt ready to feed the next cartridge. When the bolt has been completely locked, the striker is free to drive forward and fire the cartridge. When the cartridge is fired the mechanism remains locked until immediately after the bullet has passed the gas port in the barrel (3-1). Thereupon a portion of the powder gases enters the gas regulator cup (3-8) and thence through a small aperture² reaches the front of the piston (8-6). The force of the expanding gases drives the piston to the rear and through the action of the rack, rewinds the mainspring (9-9). During the backward motion, the striker post, which is also carried on the rack, moves

¹ In 1918 the *Musketenbataillone* were reformed as ordinary heavy machine-gun units.

² The function of the gas regulator cup is to act as a well for any solid matter carried in the gas and to prevent fouling of the gas chamber. The size of the aperture can be adjusted as required.

about one inch to the rear in a straight slot in the bolt, which, therefore, it does not affect while the bullet is traversing the final space between the gas port and the muzzle; but after the striker post has passed through the straightway of the bolt, it comes in contact with the right side in the cam slot in the bolt and unlocks the bolt and drives it to the rear. In unlocking the bolt is rotated and the locking lugs come into line with the guide slots in the receiver. Lastly the extractor (4-3) withdraws the empty cartridge case which is thrown out by the ejector (2-3), a flat lever pivoted in the centre and actuated by the feed operating stud (4-1) striking its rear end. This stud,

heavy machine-gun (M.G. 08), which is of the Maxim type, without any change in the essentials of the system (for which see MACHINE-GUN, 17.237). A serviceable light machine-gun was made in large quantities and with the least possible delay, and the German authorities determined to lighten the existing material, for which manufacturing facilities were already available, rather than embark on the experiments and tool and gauge making that would have been necessary if a new type had been

FIG. 14.—Lewis Machine-Gun.

which is carried by the bolt, also acts on the underside of the feed operating arm (7-5) and moves the arm to the left. By means of this arm and the feed pawl (7-2) that it carries, a cartridge from the magazine is brought under the cartridge guide (6-24) and into the feeding position in the feed-way in the top of the receiver and is partially turned so as to bring the next cartridge into position, being held in its new position by the stop pawl (6-7), and by the rebound pawl (6-8). The rearward motion of the mechanism is arrested when the bolt comes against the butt tang of the stock, and the bolt, rack, etc., then again move forward under the action of the mainspring, and the cycle of operation is repeated for each shot until the magazine is empty or the trigger is released. When the last cartridge is fired from the magazine, the bolt goes forward and locks with no cartridge in the barrel.

The magazine is a round corrugated pan about 8 in. in diameter carrying 25 upright separator pins. This pan is mounted on an aluminum centre having annular grooves with a spiral step connecting each groove, into which the front end of the cartridge fits. The cartridge, being held from rotating by the separator pins, is fed along these grooves up the steps into the gun when the pan is revolved around the magazine centre. The pan is loaded by means of a special loading tool. The feeding of the cartridges being positive instead of depending on springs or gravity, the gun can be used when turned at any angle or upside down.

The Lewis machine-gun operates automatically, single shots being fired by quickly releasing the trigger after each shot.

In aircraft the Lewis gun is used as a "flexible gun," i.e., a gun mounted (usually in the observer's pit) so as to fire in any direction in elevation or azimuth. The main differences between the ground type and the aircraft type gun are that the latter has no radiator or radiator casing, has a spade or stirrup-shaped hand-grip in lieu of the shoulder stock, and uses a 97-round magazine. A more efficient type of recoil check is also provided. This consists of a muzzle attachment which is arranged to deflect the powder gases so that they pass out practically at right angles to the axis of the bore. In this way a pressure against the muzzle piece tends to counteract recoil.

No cooling device is provided with the aircraft gun, inasmuch as the fire is in short bursts only and the speed of the aeroplane and the temperature at high elevations provide ample cooling. The aircraft gun fires at a rate of about 750 shots per minute, this higher speed being gained by increasing the gas pressure acting on the piston and the strength of the mainspring which returns the mechanism.

German Light Machine-Guns 08/15 and 08/18.—The German light machine-gun 08/15 is simply a modification of the standard

sought for. In consequence, the differences between the 08 and the 08/15 are very few. The diameter and contents of the water-jacket are considerably smaller in the light gun than in the 08. Instead of the tripod or sleigh mount, there is a shoulder stock and bipod, and a trigger release and handgrips replace the twin handles and firing gear. Ammunition is belt-fed as in the heavy gun, but the belt (100 rounds) is wound on a reel inside a drum attached to the right of the gun. The weight of the gun with water-jacket filled and bipod, is 40½ lb., or in action with drum and filled belt 51½. The Dreyse water-cooled light machine-gun was also used. Its weight was slightly less than that of the 08/15.

Guns of this weight, however, though they might be sufficiently mobile for trench warfare battles, were evidently too heavy for the more open warfare of 1917 and especially 1918, and a new and lighter model called the 08/18 was brought out. In this instead of the water-jacket there is a barrel casing with numerous holes to facilitate air circulation round the barrel. This abolition of positive cooling by water reduced the possibility of sustained fire almost to that of an automatic rifle, but independence of water supply greatly reduced freedom of manoeuvre and the actual reduction in the weight of the gun was considerable (32 lb. as against 40½ in the 08/15).

This gun had been introduced only for cavalry and cyclists when the Armistice was signed. Had the war continued, it would no doubt have replaced the water-cooled weapons entirely.

The Bergmann Light Machine-Gun (fig. 15) in the German army, variously called L.M.G. and L.M.G. 15 n A, is a recoil-operated air-cooled, belt-fed machine-gun, weighing 30 lb. with bipod mount and sling, and fires about 600 shots a minute.

A barrel casing (91) is provided which carries the barrel and also serves as a housing in which the barrel recoils. The cooling of the barrel is assisted by rings which are formed on the barrel to increase the radiating surface. A handle (92) is provided to facilitate carrying the weapon short distances. The belt is fed through the feed-box opening (93) as in the Maxim and other heavy machine-guns.

The principal features of the Bergmann machine-gun are a small cylindrical service-rifle type of bolt and extractor, which may be

operated by hand by means of a bolt handle (95); and an accelerator which is in the form of a cam lever, which acts against the bolt and barrel extension during the forward movement of the bolt, helping to push the barrel extension and barrel forward as the bolt advances under the action of the heavy recoil spring.

The gun is provided with a trigger and handgrip, a shoulder butt and a bipod, which is attached to the trunnion (96).

The front sight (97) is very high, owing to the low position of the barrel in the receiver and to the feed mechanism in cover. A tubular sight with a hole about one-fourth of an inch in diameter is attached by a bracket to the side of the gun for close-range shooting and for tank work. It will be noted that several features of this gun were adopted in the L.M.G. 08/18.

In the German army Bergmann guns formed the armament of the so-called "Light Machine Gun Detachments," mounted units created in 1916 for the Rumanian campaign. The use of this gun, however, seems to have been discontinued towards the end of the war, the weapons remaining serviceable being handed over to Turkey.

FIG. 15.—Bergmann Light Machine-Gun.

Machine Carbine-Pistols.—The idea of securing more accurate shooting from a pistol by fitting it with a shoulder stock and lengthening the barrel is an old one, and one well-known modern example is the Mauser pistol (for description see 21.657-8). But while in the pistol proper, from the nature of the arm and its uses, all modern development has been in the direction of perfecting the semi-automatic action (see PISTOL), there arose in the World War a need for some weapon lighter and handier than the rifle yet capable of developing an intensely rapid fire at short ranges. The outcome of this need was a class of firearm which at present has few representatives and no recognized generic title, but is very interesting. In the absence of an accepted designation, these may be called machine carbine-pistols.

FIG. 16.—Bergmann Pistol-Gun.

In this field the precursors appear to have been the Italians. The *pistola mitratrice Fiat* (Fiat mitrailleuse pistol) was largely used by them as a substitute for the light machine-gun, no doubt because extreme lightness both in the gun and its ammunition was essential in an automatic arm for mountain warfare. The "machine pistol" is fitted with a small shield which also serves as a mounting, though the weapon can be used in the hands, if necessary. It is double-barrelled, each barrel having a separate box magazine of 25 rounds above the receiver. It is gas-operated and air-cooled. The bolt and its dependent parts are supported but not positively locked on firing. It weighs 14 lb. without shield, takes 9 mm. pistol ammunition, and is sighted to 500 metres. An outstanding feature is the very high rate of fire. Both magazines (50 rounds) are fired in two seconds, and with highly trained loaders and a full supply of magazines it is said that 1,000 rounds can be delivered in a minute. This extreme rate, in spite of certain advantages, militates against steadiness and accuracy, especially with so slight a mounting. Nevertheless, according to the Germans the weapon proved trustworthy and effective.

The *Bergmann Pistol-Gun* (fig. 16), on the other hand, was intended not to replace the light machine-gun but to provide

artillerymen and machine-gunners with a handy personal weapon capable of intense fire power in emergencies. It originated in the pistol proper. The German service pistol 08 (Borchardt-Luger) used by specialists, who were not armed with the rifle, was fitted with a snail magazine (see PISTOL) allowing of 32 shots, the wooden holster being attached to the handgrip as a shoulder piece as in the Mauser pistol above alluded to, if accurate fire was required. The success of this arrangement led to the introduction of the Bergmann pistol-gun (officially, *Machine-Pistol 18 I.*), which in spite of its name is rather a carbine than a pistol, as an infantry weapon pure and simple.

This arm shoots 9 mm. pistol ammunition at the rate of about 540 shots per minute. The gun weighs 9 lb. 6 oz. without the magazine drum, which itself weighs 1 lb. 8 oz. empty. It is recoil-operated and air-cooled, and has an 8-in. barrel, protected by a casing perforated to allow circulation of air. The magazine (32 shots) is of the snail type (see PISTOL). The breech mechanism is of the "blow-back" class in which on firing the inertia of the bolt, the compressing of the mainspring, and friction of the cartridge in the chamber momentarily hold the action firm. The gun fires when the bolt reaches its forward position as the striker projects through the face of the bolt, and is cocked when the mainspring is compressed and the bolt drawn to the rear. This has the advantage that the chamber is always left empty but the forward movement of the heavy bolt after pulling the trigger is liable to disturb the aim. The gun is sighted to 200 metres only. This gun was only brought into use just before the Armistice.

FIG. 17. } Thompson Sub-Machine-Gun.
FIG. 18. }

The *Thompson Sub-Machine-Gun* (figs. 17 and 18) is an interesting type of a very light portable automatic weapon which shoots a .45-calibre pistol cartridge. The action is semi-automatic or automatic at will. The rate of fire when used as an automatic is 800 to 1,500 shots per minute. The weapon is about 23 in. in length, weighs 7.5 lb., and uses a straight magazine (fig. 18) holding 20 cartridges in staggered rows, or drum magazines holding 50 or 100 cartridges (fig. 17).

The novel feature of this weapon is the angular wedge breech closure which utilizes the force of adhesion developed by the heavy breech pressure to lock the breech. The principle, developed by Comm. Blish of the U.S. navy, has been briefly stated as follows:

"In any breech closure consisting of a breech plug in a suitable housing and having two pressure-resisting surfaces, the forward surface disposed normally to the axis of the bore, and the rear surface inclined thereto and bearing upon a suitable surface of the housing the force of adhesion will under heavy pressure immovably fix the breech block, but at a comparatively small pressure (whose value depends upon the inclination of the two surfaces) the force of adhesion ceases to act and the breech block is rendered free to move under the influence of the forces then existing."

The principle permits the use of a very simple breech-locking mechanism, the essential element being a bolt (98) having an angular slot cut in the under side, into which the lock (99) is free to slide, and housing or receiver (100) having a slot (101) into which a projection on the lock engages when the bolt is in its firing position. Under high pressure the lock firmly adheres to the receiver shoulder and

prevents the bolt from being blown to the rear. When the pressure is reduced, the adhesion ceases, and the lock, actuated by the remaining pressure, automatically slides upward and clear of its retaining shoulder while the bolt moves rearward against the recoil spring (102) and cocks the firing pin.

When the weapon is cocked the entire bolt group is held by the sear (104) in a retracted position, as shown in fig. 17. On the trigger being pulled the bolt, driven forward by the recoil spring, pushes a cartridge into the chamber. During the forward motion of the bolt the hammer (103) strikes a shoulder of the receiver and rotates on the hammer pin, its top end strikes the firing pin and the cartridge is fired. Firing is discontinued by releasing the trigger; the sear (104) then engages the bolt in its retracted position, leaving the chamber empty. By means of the disconnector (105) the weapon can be made semi-automatic at will. When the magazine is emptied, the trip (106) allows the sear to engage the bolt in a rear position ready to feed and fire again when the trigger is pulled. Sights graduated to 600 yd. are provided.

The sub-machine-gun is intended as an auxiliary weapon for trench use and for close fighting generally. It has been adopted also by the police of several American cities for use as a riot weapon, both for shot and ball cartridges.

(H. O'L.)

RIGHI, AUGUSTO (1850-1920), Italian physicist, was born at Bologna Aug. 27 1850. Details of his experimental work in magnetism and the problems of electricity and light are given in 17,380, 301 and 346, 6,859, 9,206, 21,936. He was specially noted for his discovery of the electrical conductivity of bismuth and other metals, and for his pioneer work in wireless telegraphy. G. Marconi was his pupil. He died at Bologna, June 8 1920.

RILEY, JAMES WHITCOMB (1853-1916), American poet (see 23,343), died at Indianapolis, Ind., July 22 1916. In 1915, by proclamation of the governor of Indiana, his birthday, Oct. 7, was observed throughout the state, in honour of "Indiana's most beloved citizen." In 1913 he issued in six volumes a biographical edition of his works.

See Clara E. Laughlin, *Reminiscences of J. W. Riley* (1916).

RIO DE JANEIRO (see 23,353).—According to the census of 1920, the pop. of the independent municipal commune, or federal district, which contains the city and is detached from the province of the same name, was 1,157,873 inhabitants. As the census of 1906 showed 811,443 inhabitants, the pop. has increased 43% in 14 years, an annual increment of 3.05 per cent. In 1920 there were 1,265 factories, large and small, with 46,953 operatives, representing a capital of nearly 270,000,000 paper milreis, and an annual production valued at about 500,000,000 milreis. In 1920 the number of buildings in the municipality was about 113,000, as against 84,375 in 1906. The federal district is governed by a prefect appointed by the president of the republic, and elects three senators and ten deputies to the national congress. The legislative power of the municipality is vested in a council consisting of 24 *intendentes* elected for three years.

The consolidated debt of the municipality in 1920 was computed at 227,089,200 paper milreis, of which 129,225,450 milreis was an external debt, and 97,863,750 milreis internal. The revenue had grown from 29,070,883 paper milreis in 1910 to 51,182,357 paper milreis in 1919.

Education.—Primary instruction is provided by the municipality, which in 1920 maintained 320 day-schools and 68 night-schools, with a matriculation of 74,111 pupils in the former and 8,662 in the latter. There are in addition 236 elementary private schools, with 19,825 pupils; over 80 receive a subvention from the Government on condition that they adopt the official curriculum and admit a certain number of children free. Secondary instruction is cared for in public lycées and in many private establishments. There is no university, but the capital possesses higher faculties of law, medicine and engineering, besides schools providing instruction in pharmacy, dentistry, commerce, music, dramatics and the fine arts. The national Government also maintains a naval academy, a military college and a preparatory school of tactics. The most important libraries are:—the National library, the best appointed in S. America; the Municipal; the Gabinete Portuguez da Leitura; that of the Lycée of Arts and Crafts; and the collections existing in the various ministries and departments.

Streets and Buildings.—During the decade 1910-20 the ambitious programme of municipal improvements inaugurated in 1903 was in large measure completed. The port works, including a sea-wall over 2 m. long, 8 ft. above mean high-tide, and lying almost entirely in deep-water, enclosing a broad reach of reclaimed land between it and the former shore-line, provide the city with the most modern facilities for loading and unloading ships. The Avenida Rio Branco

(formerly Avenida Central), built through the heart of the city in 1904, is now one of the handsomest thoroughfares in the western hemisphere. Over a mile long from N. to S., it is lined with fine private and public buildings. The military, naval and jockey clubs are situated there, and also the offices of some of the principal newspapers, such as the *Jornal do Comercio* and *O Pais*, besides many fashionable shops, cafés and business places. At the southern end is a group of elegant State edifices, the Municipal theatre, the Monroe palace, and the National library and Academy of Fine Arts. It is adorned with three rows of trees, and with broad sidewalks of white and black stone set to form figures in mosaic, as in Lisbon. For this both material and workmen were imported from Portugal. The Municipal theatre, designed in 1904, cost over £2,000,000, although it seats but 1,700 people. The building which houses the National library, opened in 1910 in commemoration of the centenary of its founding (1808), is also a notable addition to the city. It is a fireproof structure of granite, marble and steel, equipped with every modern library appliance.

One of the important developments of Rio de Janeiro has been in suburban road-building. As the hills come practically to the bay and sea, construction is difficult, but great progress has been made and a 40-m. motor drive over perfect roads is now joining all the famous beaches with Tijuca and the city. The magnificent bay-side drive, the Avenida Beira-Mar, with its double motor track and intervening lawns and gardens, is particularly remarkable.

Sanitation.—The city, formerly a hotbed of yellow fever and smallpox, has become one of the healthiest tropical cities in the world. The death-rate has fallen to about 20 per 1,000. This is the result of a campaign of scrupulous cleanliness, rigid enforcement of sanitary measures and scientific eradication of mosquitos and other germ-bearing insects, inaugurated under the direction of the celebrated Brazilian scientist, Dr. Oswaldo Cruz, in the first administration of President Rodrigues Alves (1903). In 1920 a law was passed by Congress creating a national department of public health, consisting of three divisions, one in charge of the federal capital.

(C. H. H.)

RIO DE ORO (see 23,357).—The area of the Spanish Sahara defined and extended by the Franco-Spanish Conventions of 1904 and 1912 is about 110,000 sq. miles. The frontiers have not been delimited. The colony proper (area, about 65,500 sq. m.) extends from lat. 21°20' N. to 26° N. The 1904 Agreement recognized a Spanish Protectorate over an area on the N. of about 34,700 sq. m., extending to lat. 27°40' N. and bounded E. by the meridian 8°40' W.; and the 1912 Agreement acknowledged the sovereign rights of Spain over this region. Still farther N. is an "occupied territory" of about 9,800 sq. m., extending to Wad Draa (lat. 28°45' N.), and forming an intermediate zone between the Spanish possessions and Morocco.

The interior has been little explored. A central volcanic tableland, the Tiris, about 1,000 ft. above sea-level, falls by terraces broken by ravines to the coastal plain and to the Segiet el Hamra on the north. To the S., the vast dunes of Azelal separate the Spanish Sahara from Mauretania (see 17,908). Wad Shebika enters the sea about 36 m. S.W. of Wad Draa and runs parallel to its lower course. The only permanent water is in brackish wells which frequently become choked. The only district likely to repay colonisation appears to be the wide basin of the Segiet el Hamra and its tributaries, whose flood-waters suffice to fertilize pasture and arable land or date-groves, as at the oasis of Smara.

There are few main tracks and a network of smaller tracks, but no roads and but few villages. Smara, 160 km. inland from C. Juby, is the most important settlement and is the headquarters of the notorious religious agitators Ma el 'Ainin and his son El Hiba. Vil Cisneros, on the Dakhla peninsula, the residence of the governor (deputy for the governor-general of the Canaries), has a garrison and fish-curing industry; pop. (1918) 529 foreigners and 495 natives, with an adjoining village of 800 negroid half-castes (Imragen). The desert population, roughly estimated at 80,000, is nomadic, fluctuating between French and Spanish territory, and is split up into pro-French and pro-Spanish partisans. In 1912, there was a general rising under El Hiba. In 1916, a small Spanish expedition occupied C. Juby, but the fishermen, of whom the chief are the Aulad Delim Arabs and their allies the Regeibat (Arabized Berbers), remained practically uncontrolled. Camels and ostriches are reared.

In 1916 the total value of imports by sea was £4,820; of exports £4,910, chiefly fish and fish products. The fishing industry would be considerable if better methods were employed. There are open roadsteads at El Maït, at the mouth of the Segiet el Hamra, and Tarfaya, about 180 km. farther north. The climate is fairly equable on the coast, but intense heat and drought prevail inland, with diurnal variations of temperature in the shade of as much as 74°. At Villa Cisneros the mean maximum summer temperature is 86° F., and the mean minimum winter 48° F.

(E. G. S.)

RISLEY, SIR HERBERT HOPE (1851-1911), English anthropologist, was born at Akeley, Bucks., Jan. 4 1851. Educated at

Winchester and New College, Oxford, he entered the Indian civil service in 1873 and he had a distinguished career; but his principal work was done in connexion with Indian ethnography, the discussion of the caste system, etc., and he published under Government auspices some important volumes of anthropometric data. He had charge of the Indian census operations of 1901. In 1910 he was appointed secretary of the judicial department of the India Office. He was made K.C.I.E. in 1907, and he died at Wimbledon Sept. 30 1911.

RITCHIE, ANNE ISABELLA, LADY (1837-1919), English writer (*see* 26.716), eldest daughter of W. M. Thackeray, died at Freshwater, I. of Wight, Feb. 26 1919. She is best remembered perhaps as the author of *Old Kensington* (1873). Amongst her other novels were *The Story of Elizabeth* (1863) and *The Village on the Cliff* (1865). She also published various volumes of biographical essays (*Madame de Sévigné*, 1881, and *A Book of Sibyls*, 1883, etc.), and contributed a most interesting series of prefaces to the Library edition of her father's works, thus supplying a substitute for the regular biography of him that he had always deprecated. Her husband, **SIR RICHMOND THACKERAY RITCHIE** (b. 1854), became permanent Under-Secretary of State for India in 1910, and died Oct. 12 1912.

RIVIÈRE, BRITON (1840-1920), English painter (*see* 23.387), died in London April 20 1920. His later works include "Aphrodite" (1902) and "Hark! Hark! the Lark" (1909), also a portrait of Lord Tennyson (1909). His eldest son, **HUGH GOLDWIN** (b. 1869), became a well-known painter; and the second son, **CLIVE** (b. 1872), a prominent physician.

RIVINGTON, FRANCIS HANSARD (1834-1913), British publisher (*see* 23.387), died July 2 1913.

RIVOIRA, GIOVANNI TERESIO (1849-1910), Italian archaeologist, was born at La Manta di Saluzzo in Piedmont Sept. 22 1849. He came of an old Piedmontese family and on his mother's side was descended from the Riccati (*see* 23.288), a family of mathematicians and architects. He took his training as an architect and engineer at the university of Turin, entered Rome with the Italian army in 1870 and thenceforth resided there, devoting his life to travel and to the study of the architecture of the later Roman Empire. In 1884 he married Edith E. Johnson of Cheltenham. He published two monumental works, *Le Origini dell' Architettura Lombarda* (1901-7, Eng. trans. 1910) and *Architettura Musulmana* (1914, Eng. trans. 1919). At the time of his death in Rome March 3 1910 he was engaged upon a third, *Architettura Romana*, which was posthumously published in Rome (1920) by his widow.

ROBERT-FLEURY, TONY (1837-1911), French painter (*see* 23.403), died in 1911.

ROBERTS, FREDERICK SLEIGH ROBERTS, EARL (1832-1914), British field-marshal (*see* 23.403). Subsequently to 1905 Lord Roberts took an active and leading part, as head of the National Service League, in the movement in favour of compulsory military service for home defence. On the outbreak of the World War he was a frequent and welcome visitor at the War Office, and shortly after the arrival of the two Indian divisions in France he crossed the Channel to visit them when the weather was cold and inclement. He was attacked by pneumonia while at the front, and he died at St. Omer on Nov. 14 1914, the title going by special remainder to his elder daughter, Aileen Mary. He was buried in St. Paul's.

Lord Roberts was a tried and brilliant commander in the field. His self-reliance and willingness to accept risks when planning operations were demonstrated by the daring advance to Kabul after the massacre of the Cavagnari Mission, and by his sloop across the Orange Free State from the Modder to Bloemfontein in Feb. 1900, abandoning his communications. That instinctive grasp of a tactical situation which stamps the great captain was displayed by him on many occasions, notably when he attacked the Afghans on the Peiwar Kotul and at Kandahar, and on the occasion of his riding on to the field of Paardeberg. His attractive personality and his natural kindliness made him a most popular chief, and, even if he hardly ranked as a military administrator of the very foremost class, his steward-

ship in the high offices that he filled in India and at home was advantageous to the army and to the State. An eminently knightly figure, Lord Roberts was a fine horseman, a great gentleman, an ardent patriot and a devout Christian.

ROBERTS, GEORGE HENRY (1869-), English Labour politician, was born at Chedgrave, Norfolk, July 27 1869. His parents removed to Norwich where he attended an elementary school and evening classes. In 1883 he was apprenticed to the trade of printer and compositor. At the expiration of apprenticeship he went to London and joined the London Society of Compositors. After a year he returned to Norwich and identified himself with the movement to organize local printers in a branch of the Typographical Association, of which he became president and ultimately secretary. He also became president of the Norwich and District Trades and Labour Council. He was elected to the Norwich School Board in 1899, being the first candidate run by the local Labour party to win a seat on a public body. In 1904 he was elected to the post of national organizer of the Typographical Association and was chosen as its parliamentary representative. He was returned as one of the members for Norwich at the general election of 1906, and has held the seat since. He was whip of the parliamentary Labour party for about eight years and a member of the executive council of the party. When the Labour party joined the Coalition movement in 1915 he became a Lord Commissioner of the Treasury; he was parliamentary secretary to the Board of Trade 1916-7; Minister of Labour, 1917-8; Food Controller, Jan. 1919. He resigned from the Government Feb. 1920.

ROBERTS, JOHN (1847-1919), English billiard-player, was born at Ardwick, Manchester, Aug. 15 1847, the son of John Roberts, also a great player of billiards. Details of the exploits both of father and son are given in 3.937. John Roberts, jun., died at Worthing Dec. 23 1919.

ROBERTSON, SIR GEORGE SCOTT (1852-1916), British soldier and administrator, was born in London Oct. 22 1852. He was educated at Westminster hospital medical school, and in 1878 entered the Indian medical service. He served through the Afghan War of 1879-80, and in 1888 was attached to the Indian Foreign Office, being employed as agency surgeon in Gilgit, on the frontier of Kashmir. In 1890-1 he travelled in Kafiristan (*see* 15.630). In 1893 he went as political agent to Chitral, and in 1895 was besieged there by hostile tribesmen (*see* 6.252). For his services he was created K.C.S.I., and appointed British agent in Gilgit. He retired from the Indian service in 1899 and returned to England. He unsuccessfully contested Stirlingshire in the Liberal interest in 1900, but was elected for Central Bradford in 1906. He died Jan. 1 1916.

ROBERTSON, SIR WILLIAM ROBERT, BART. (1850-). British field-marshal, was born, of poor parentage, in Linco. Sept. 14 1850. He enlisted as a private in the 16th Lancers in 1877 and served in the ranks of that regiment until 1888, when he won a commission in the 3rd Dragoon Guards, then in India. On joining he eagerly studied his profession in all its branches and he was very successful in learning the native languages. He was selected to be railway staff officer in the Miranzai and Black Mountain operations of 1891, and in the following year he joined the intelligence department at Simla; while on its staff he carried out a reconnaissance to the Pamirs, and in 1895 served with the Chitral Relief Force, being wounded and receiving the D.S.O. He passed through the Staff College in 1897-8—the first officer risen from the ranks to do so—and then, after a few months at the War Office, went out to S. Africa on the intelligence staff; he accompanied Lord Roberts on his advance from Cape Colony into the Transvaal and was promoted brevet lieutenant-colonel for his services. He spent the period from 1901 to 1907 at the War Office, being promoted colonel in 1903, and he then went to the staff at Aldershot, where he spent three years. In 1910 he was appointed commandant of the Staff College, was shortly afterwards promoted major-general, and in 1913 became director of military training at the War Office.

On mobilization of the army for the World War, Sir W. Robertson—he had been given the K.C.V.O. in 1913—was nominated

quartermaster-general of the Expeditionary Force; he filled that appointment most successfully for five months and then, in Jan. 1915, he became chief of the general staff to Sir J. French. In the autumn of that year he was promoted lieutenant-general for distinguished service and in the following Dec. was brought back to the War Office to take up the post of chief of the imperial general staff. There he immediately introduced great improvements in the office organization, and during the first year and a half of his holding the appointment he was successful in keeping the general control of operations on sound lines. While convinced that the western front represented the decisive theatre of war, and fully aware how mischievous was dispersion of force in principle, he saw to it that, where circumstances unfortunately rendered operations in distant regions unavoidable, the commanders on the spot were furnished with what was deemed essential to achieve success—with the result that the position of affairs in Mesopotamia, on the Suez frontier and in E. Africa was completely transformed within a very few months of his taking up his task. His services were recognized by his being promoted general in 1916 and by his being given the G.C.B. in 1917. He had, however, always experienced some trouble in sufficiently impressing upon the Government that the war could only be won in the west, and in the later months of 1917 he found it more and more difficult, in view of the somewhat disappointing results obtained by Allied offensives in France and Flanders, to persuade the War Cabinet that diversion of fighting resources to Alexandretta, or to Palestine, or to Macedonia, or to the Austro-Italian frontier, endangered prospects of victory at the decisive point and might lead to disaster near home. His anxieties were increased by the manner in which the problem of man-power was treated. He moreover foresaw that the plan of having a supreme war council composed of military representatives of the Allies, such as was introduced towards the end of the year, was an unworkable one. Finally in Feb. 1918 he resigned—just one month before the success that attended the great German offensive of March proved how correct had been his appreciation of the situation. He was given charge of the eastern command, and three months later he succeeded Lord French as commander-in-chief in Great Britain. On the final distribution of honours for the war he was rewarded with a baronetcy and grant of £10,000, and he was nominated G.C.M.G. From April 1919 to March 1920 he commanded the British troops on the Rhine, and, after relinquishing that appointment on the force being reduced, he was promoted field-marshal.

See his autobiographical volume *From Private to Field-marshal* (1921).

ROBINS, ELIZABETH (1865–), Anglo-American novelist and actress, was born at Louisville, Ky., Aug. 6 1865, and educated at Zanesville, O. She had had her early training as an actress in America with the Boston Museum stock company, and afterwards with Edwin Booth. Coming to London she first appeared in *The Real Little Lord Fauntleroy* in 1889, and between 1890 and 1896 she played in most of Ibsen's plays, in which she established her position on the stage. In 1902 she was Lucretia in Stephen Phillips's *Paolo and Francesca* at the St. James's theatre, London. Her first novels, *George Mandeville's Husband* (1894), *The New Moon* (1895) and *Below the Salt* (1896), appeared over the pseudonym of C. E. Raimond, but in 1898 the success of *The Open Question* led to her publishing in her own name, her reputation as a writer being maintained in *The Magnetic North* (1904); *A Dark Lantern* (1905); *Come and Find Me* (1908); *Camilla* (1918) and *The Messenger* (1920). She took an active part in the agitation for woman suffrage. Her play *Votes for Women* was acted at the Court theatre, London, in 1907.

ROBINSON, EDWIN ARLINGTON (1869–), American poet, was born at Head Tide, Me., Dec. 22 1869. From the public schools of Gardiner, Me., he proceeded in 1891 to Harvard, but withdrew after two years to take a business position in New York City. From 1905 to 1910 he was connected with the N.Y. Customs House, and then returned to Gardiner to devote his time to literature, and especially to poetry. He became a member of the National Institute of Arts and Letters.

His works include *The Torrent and the Night After* (1896); *The Children of the Night* (1897); *Captain Craig* (1902); *The Town down the River* (1910); *Van Zorn* (1914, a play); *The Porcupine* (1915, a play); *The Man against the Sky* (1916); *Morlin* (1917); *Lancelot* (1920); *The Three Taverns* (1920); *Avon's Harvest* (1921); *Collected Poems* (1921).

ROBSON, WILLIAM SNOWDON ROBSON, BARON (1852–1918), English lawyer and lord of appeal, was born at Newcastle-upon-Tyne Sept. 10 1852. He was educated at Caius College, Cambridge, where he took his degree in 1877. In 1880 he was called to the bar and entered politics, sitting as Liberal member for Bow and Bromley from 1885 to 1886, and for South Shields from 1895 to 1910. He earned a reputation as a distinguished and energetic advocate, and became a Q.C. in 1892. In 1905 he was knighted, and became solicitor-general in Sir Henry Campbell-Bannerman's Government, being made Attorney-General in 1908. In 1910 he was made a privy councillor, and became a lord of appeal and life peer. He resigned his office in 1912, and died at Battle, Sussex, Sept. 11 1918.

ROBY, HENRY JOHN (1830–1915), English scholar (see 23.424), died at Grasmere Jan. 2 1915. He contributed a chapter on Roman law to the second volume of the *Cambridge Medieval History* in 1913.

ROCHFORD, HENRI (1830–1913), French politician (see 23.426), died at Aix-les-Bains June 30 1913.

ROCKEFELLER, JOHN DAVISON (1839–), American capitalist (see 23.433), continued after 1910 to live a retired life, and to give great sums for charitable and educational purposes. In 1913 the Rockefeller Foundation was chartered under the laws of the state of New York (Congress having refused to enact the legislation necessary for a national charter) "to promote the well-being of mankind throughout the world." To this, the most extensive of his benefactions, Rockefeller had given in all \$180,000,000 by 1921. The income and \$10,000,000 of the original gifts were expended from time to time by its trustees. With increasing definiteness the Rockefeller Foundation focussed its efforts in the fields of medical education and public health. After 1913 it supported by appropriations the International Health Board, an independent organization engaged, in cooperation with governmental agencies, in demonstrations for the control of hookworm disease in 14 southern states of the United States and 22 foreign states or countries; of yellow fever in five South and Central American countries and of malaria in 10 southern states of the United States. In addition, the International Health Board, with funds provided by the Rockefeller Foundation, organized in 1917, partly as a war measure, the Commission for Prevention of Tuberculosis in France; this commission conducted in limited areas, as demonstrations, vigorous campaigns of popular education in hygiene, and provided for the training of French women as health visitors. By the end of 1920 arrangements were under way for the continuation of the work of the Commission by French authorities. In 1914 the Rockefeller Foundation established the China Medical Board to promote the development of scientific medicine and hygiene in China through medical schools, hospitals, and training schools for nurses. In 1919 the Peking Union Medical College, founded by it, was opened together with pre-medical and nurse-training schools. Gifts have been made also to other institutions in China offering pre-medical courses, and to hospitals. In 1920 the Foundation established a Division of Medical Education, through whose advice large pledges of money were made for the development of medical centres in London, and in various cities of Canada. As a part of its public health work, the Rockefeller Foundation also made grants for the support of schools of hygiene at Johns Hopkins University, Baltimore, and at the university of São Paulo, Brazil. A special feature of the work was provision for fellowships to persons from many different countries engaged in study in medical education and public health. During the year 1920, 71 fellows from 13 countries (including the United States) were supported. During the World War the Foundation contributed to war work agencies; and before crystallization of its general policy of limiting its work to

medical education and public health, it made appropriations to a number of objects in other fields.

To the General Education Board, the next largest of his charities, Rockefeller had given up to Dec. 1920 over \$115,000,000. By the close of the fiscal year 1920, this Board had contributed more than \$32,000,000 towards the endowments of different colleges, excluding professional departments, the general practice being to make gifts contingent upon the raising of additional sums. Among medical schools which received help were Washington University, \$2,345,000; Johns Hopkins, over \$2,200,000; University of Chicago, \$2,000,000 (joint fund with the Rockefeller Foundation, 1916); Vanderbilt, \$4,000,000 (1919); Rochester, \$5,000,000 (1920); Yale Medical School, \$1,582,000; and the Meharry Medical College (for negroes), Nashville, Tenn., \$150,000 (1920). The Board's facilities for aiding medical education were greatly increased in 1919 by a further gift from Rockefeller of \$20,000,000, both principal and interest to be expended in the United States during the next 50 years. In 1919 it gave \$500,000 towards the endowment of the Graduate School of Education at Harvard, opened the following year; and in 1920 appropriated \$1,000,000 to the proposed building fund of Teachers' College, Columbia University, the largest gift yet made to any institution for training teachers. To the Rockefeller Institute for Medical Research, New York, Rockefeller gave in all upwards of \$25,000,000. In Nov. 1920 announcement was made that he had given more than \$63,000,000 to the Laura Spelman Rockefeller Memorial, New York, largely for the continuing of charities in which Mrs. Rockefeller, who died in 1915, had been interested. By that time more than \$8,000,000 had already been appropriated, chiefly for the benefit of women and children.

It was estimated at the beginning of 1921 that the total amount given by Mr. Rockefeller for philanthropic and charitable purposes exceeded \$500,000,000. Nearly four-fifths of this had gone to the four great charitable corporations which he created: The Rockefeller Foundation, General Education Board, The Laura Spelman Rockefeller Memorial and the Rockefeller Institute for Medical Research. Quite as significant as the magnitude of these gifts was the fact that they were free from all restrictions, having been given for the general purposes of the respective corporations, the trustees of which have power to dispose of the principal as well as the income. As the corporate purposes of these organizations are extremely broad, and the gifts are free from restrictions, they will always be adaptable to the changing needs of the future generations. While it was probably true that Mr. Rockefeller was the richest man in the world, it would appear, in view of the statements made by competent authorities, that his wealth in 1921 was less than \$500,000,000, and that in making his gifts he had drawn very heavily upon capital as well as income.

RODIN, FRANÇOIS AUGUSTE (1840-1917), French sculptor (see 23.447), presented in Nov. 1914 20 examples of his work in bronze, including "L'Enfant prodigue," "La Muse," "France," "Cybèle," "L'ange déchu," "Balzac," and a bust of Mr. George Wyndham, to the Victoria and Albert museum, London, as a token of his admiration for the deeds of the British army. In 1916 Rodin presented all the works remaining in his possession to France, and in 1917 a replica of "The Burghers of Calais" was placed in the garden adjoining the House of Lords. He died at Meudon, near Paris, Nov. 17 1917.

RODZIANKO, MICHAEL VASSILIEVICH (1859-), Russian politician, was born in 1859 and belonged to a family of great landowners. At the age of 19 he joined the Horse Guards, but he soon resigned and retired to his large estates in the government of Novgorod. He took an active part in local life and was also a member of the conferences of Zemstova and Towns. In 1905 he was elected member of the First Duma and was re-elected at all subsequent elections. He joined the right wing of the Octobrist (Moderate Liberal) party, and with the support of the Conservatives was elected president of the Third Duma after the resignation of A. Guchkov in March 1911. Later he was re-elected president of the Fourth Duma, and took an important

part in the struggle for constitutional changes in the Government of Russia. He strongly opposed the reactionary policy of the Imperial Government, and always defended the rights and privileges of the Duma. By the force of events Rodzianko was placed at the head of the national movement at the moment of the revolution, and, as president of the Provisional Committee of the State Duma, he sent a telegram to the Tsar pointing out the necessity of his abdication. But he had no real influence on the course of the revolution. He played for some time a purely decorative rôle, receiving telegrams of congratulation and delivering speeches, but he soon disappeared from the stage. After the Bolshevik revolution, he made his way to the south of Russia, where he took part in different anti-Bolshevik organizations and bodies. Later he emigrated to Germany.

ROGERS, BENJAMIN BICKLEY (1828-1899), English classical scholar, was born at Shepton Montagu, Som., Dec. 11 1828. Educated at Wadham College, Oxford, he was elected a fellow of the college in 1852 and was called to the bar in 1856. There he was on the high road to success, when increasing deafness obliged him to retire and devote himself exclusively to literature. He translated all the plays of Aristophanes, reproducing the Greek metres in the English version. He died at Twickenham Sept. 22 1899.

ROGERS, JAMES GUINNESS (1822-1911), British Nonconformist divine, was born at Enniskillen, Ireland, Dec. 29 1822. He was educated at Silcoates school, Wakefield, and Trinity College, Dublin. From 1865 to 1900 he was a minister of the Clapham Congregational church. He is best remembered for his close association with Dr. Dail in the Liberal-Nonconformist education and disestablishment campaigns of 1865-75, and for his friendship with Mr. Gladstone and Lord Rosebery, who consulted him as the foremost representative of Nonconformist statesmanship. He died at Clapham Aug. 20 1911.

ROLLAND, ROMAIN (1866-), French man of letters, was born at Clamecy, Nièvre, Jan. 29 1866. He was educated at Clamecy, and later in Paris, where he had a distinguished academic career. From 1889-91 he was a member of the French School in Rome, in 1892 went with an archaeological expedition to Italy, and in 1895 was appointed professor of the history of art at the École Normale Supérieure, later occupying the same position at the Sorbonne, where he introduced the study of the history of music. He produced many critical and historical works, among them *Histoire de l'Opéra en Europe avant Lulli et Scarlatti* (1895); *Des Causes de la Décadence de la Peinture italienne* (1895); and *Le Théâtre du Peuple* (1903); besides studies on Millet (1902); *Beethoven* (1903) and *Michel-Ange* (1906). His most famous work, however, is the romance of *Jean Christophe*, the biography of a German musician, one of the most remarkable productions of the present day. The work is in three series, *Jean Christophe*, *Jean Christophe à Paris* and *La Fin du Voyage*. It appeared in 10 volumes, the first, *L'Aube*, in 1904, and the last, *La Nouvelle Journée*, in 1912. A series of articles published by Romain Rolland in the *Journal de Genève* during Sept. and Oct. 1914 created an extremely bad impression in France owing to the "defeatist" attitude of the author. His later works include *Au-dessus de la Mêlée*, of which the ninth edition appeared in 1915; *Colas Brangnon*, a novel (1918); *Les Précurseurs* (1919) and *Voyage musical aux pays du passé* (1919).

See Jan Romein, *Romain Rolland* (1918); I. Debran, *M. R. Rolland, initiateur du défaitisme* (1918); W. Kuechler, *Romain Rolland* (1919).

ROMER, SIR ROBERT (1840-1918), English judge, was born in London Dec. 23 1840. He was educated privately and at Trinity Hall, Cambridge, where he was senior wrangler and Smith's prizeman in 1863. From 1865 to 1866 he was professor of mathematics at Queen's College, Cork, but in 1867 was called to the bar, becoming in 1881 a Q.C. and in 1884 a bencher of Lincoln's Inn. In 1890 he was raised to the bench of the Chancery division and knighted, and in 1899 became a lord justice of appeal. He presided over one of the inquiries made after the South African War, and was also a member of the royal commission on university education. He received the G.C.B. in 1901

quartermaster-general of the Expeditionary Force; he filled that appointment most successfully for five months and then, in Jan. 1915, he became chief of the general staff to Sir J. French. In the autumn of that year he was promoted lieutenant-general for distinguished service and in the following Dec. was brought back to the War Office to take up the post of chief of the imperial general staff. There he immediately introduced great improvements in the office organization, and during the first year and a half of his holding the appointment he was successful in keeping the general control of operations on sound lines. While convinced that the western front represented the decisive theatre of war, and fully aware how mischievous was dispersion of force in principle, he saw to it that, where circumstances unfortunately rendered operations in distant regions unavoidable, the commanders on the spot were furnished with what was deemed essential to achieve success—with the result that the position of affairs in Mesopotamia, on the Suez frontier and in E. Africa was completely transformed within a very few months of his taking up his task. His services were recognized by his being promoted general in 1916 and by his being given the G.C.B. in 1917. He had, however, always experienced some trouble in sufficiently impressing upon the Government that the war could only be won in the west, and in the later months of 1917 he found it more and more difficult, in view of the somewhat disappointing results obtained by Allied offensives in France and Flanders, to persuade the War Cabinet that diversion of fighting resources to Alexandretta, or to Palestine, or to Macedonia, or to the Austro-Italian frontier, endangered prospects of victory at the decisive point and might lead to disaster near home. His anxieties were increased by the manner in which the problem of man-power was treated. He moreover foresaw that the plan of having a supreme war council composed of military representatives of the Allies, such as was introduced towards the end of the year, was an unworkable one. Finally in Feb. 1918 he resigned—just one month before the success that attended the great German offensive of March proved how correct had been his appreciation of the situation. He was given charge of the eastern command, and three months later he succeeded Lord French as commander-in-chief in Great Britain. On the final distribution of honours for the war he was rewarded with a baronetcy and grant of £10,000, and he was nominated G.C.M.G. From April 1919 to March 1920 he commanded the British troops on the Rhine, and, after relinquishing that appointment on the force being reduced, he was promoted field-marshal.

See his autobiographical volume *From Private to Field-marshal* (1921).

ROBINS, ELIZABETH (1865–), Anglo-American novelist and actress, was born at Louisville, Ky., Aug. 6 1865, and educated at Zanesville, O. She had had her early training as an actress in America with the Boston Museum stock company, and afterwards with Edwin Booth. Coming to London she first appeared in *The Real Little Lord Fauntleroy* in 1889, and between 1890 and 1896 she played in most of Ibsen's plays, in which she established her position on the stage. In 1902 she was Lucretia in Stephen Phillips's *Paolo and Francesca* at the St. James's theatre, London. Her first novels, *George Mandeville's Husband* (1894), *The New Moon* (1895) and *Below the Salt* (1896), appeared over the pseudonym of C. E. Raimond, but in 1898 the success of *The Open Question* led to her publishing in her own name, her reputation as a writer being maintained in *The Magnetic North* (1904); *A Dark Lantern* (1905); *Come and Find Me* (1908); *Camilla* (1918) and *The Messenger* (1920). She took an active part in the agitation for woman suffrage. Her play *Votes for Women* was acted at the Court theatre, London, in 1907.

ROBINSON, EDWIN ARLINGTON (1869–), American poet, was born at Head Tide, Me., Dec. 22 1869. From the public schools of Gardiner, Me., he proceeded in 1891 to Harvard, but withdrew after two years to take a business position in New York City. From 1905 to 1910 he was connected with the N.Y. Customs House, and then returned to Gardiner to devote his time to literature, and especially to poetry. He became a member of the National Institute of Arts and Letters.

His works include *The Torrent and the Night After* (1896); *The Children of the Night* (1897); *Captain Craig* (1902); *The Town down the River* (1910); *Van Zorn* (1914, a play); *The Porcupine* (1915, a play); *The Man against the Sky* (1916); *Morlin* (1917); *Lancelot* (1920); *The Three Taverns* (1920); *Avon's Harvest* (1921); *Collected Poems* (1921).

ROBSON, WILLIAM SNOWDON ROBSON, BARON (1852–1918), English lawyer and lord of appeal, was born at Newcastle-upon-Tyne Sept. 10 1852. He was educated at Caius College, Cambridge, where he took his degree in 1877. In 1880 he was called to the bar and entered politics, sitting as Liberal member for Bow and Bromley from 1885 to 1886, and for South Shields from 1895 to 1910. He earned a reputation as a distinguished and energetic advocate, and became a Q.C. in 1892. In 1905 he was knighted, and became solicitor-general in Sir Henry Campbell-Bannerman's Government, being made Attorney-General in 1908. In 1910 he was made a privy councillor, and became a lord of appeal and life peer. He resigned his office in 1912, and died at Battle, Sussex, Sept. 11 1918.

ROBY, HENRY JOHN (1830–1915), English scholar (see 23.424), died at Grasmere Jan. 2 1915. He contributed a chapter on Roman law to the second volume of the *Cambridge Medieval History* in 1913.

ROCHFORD, HENRI (1830–1913), French politician (see 23.426), died at Aix-les-Bains June 30 1913.

ROCKEFELLER, JOHN DAVISON (1839–), American capitalist (see 23.433), continued after 1910 to live a retired life, and to give great sums for charitable and educational purposes. In 1913 the Rockefeller Foundation was chartered under the laws of the state of New York (Congress having refused to enact the legislation necessary for a national charter) "to promote the well-being of mankind throughout the world." To this, the most extensive of his benefactions, Rockefeller had given in all \$180,000,000 by 1921. The income and \$10,000,000 of the original gifts were expended from time to time by its trustees. With increasing definiteness the Rockefeller Foundation focussed its efforts in the fields of medical education and public health. After 1913 it supported by appropriations the International Health Board, an independent organization engaged, in cooperation with governmental agencies, in demonstrations for the control of hookworm disease in 14 southern states of the United States and 22 foreign states or countries; of yellow fever in five South and Central American countries and of malaria in 10 southern states of the United States. In addition, the International Health Board, with funds provided by the Rockefeller Foundation, organized in 1917, partly as a war measure, the Commission for Prevention of Tuberculosis in France; this commission conducted in limited areas, as demonstrations, vigorous campaigns of popular education in hygiene, and provided for the training of French women as health visitors. By the end of 1920 arrangements were under way for the continuation of the work of the Commission by French authorities. In 1914 the Rockefeller Foundation established the China Medical Board to promote the development of scientific medicine and hygiene in China through medical schools, hospitals, and training schools for nurses. In 1919 the Peking Union Medical College, founded by it, was opened together with pre-medical and nurse-training schools. Gifts have been made also to other institutions in China offering pre-medical courses, and to hospitals. In 1920 the Foundation established a Division of Medical Education, through whose advice large pledges of money were made for the development of medical centres in London, and in various cities of Canada. As a part of its public health work, the Rockefeller Foundation also made grants for the support of schools of hygiene at Johns Hopkins University, Baltimore, and at the university of São Paulo, Brazil. A special feature of the work was provision for fellowships to persons from many different countries engaged in study in medical education and public health. During the year 1920, 71 fellows from 13 countries (including the United States) were supported. During the World War the Foundation contributed to war work agencies; and before crystallization of its general policy of limiting its work to

on a "landslide" for him. A speech by Roosevelt a few weeks earlier before the Ohio Constitutional Convention, advocating the "Recall" of judicial decisions, also gave alarm to some men who might otherwise have supported him. Once organized, the Taft forces were able to carry through the report of the Committee on Credentials, which assigned them a safe majority.

Roosevelt himself had come to Chicago a few days before the Convention, and was the centre of the hardest battle of his life. He rallied his supporters, and addressed an enormous public meeting, ending his speech with "We stand at Armageddon, and we battle for the Lord." Most of his followers stood by him; but they could not break down the walls of precedent and conservatism. The Roosevelt delegates, on their leader's request, remained in the Convention until the end, but refused to vote on the nomination; and Taft was duly nominated for a second term by the vote of about two-thirds of the Convention.

Roosevelt was a party man, who had stood by the party in 1884 when many of his friends bolted. His standpoint in 1912 was that he was trying to save the Republican party from a ruinous yielding to the forces of organized wealth and reaction. He was also a fighter, and felt himself deprived, by technicalities and personal hatreds, of an honour which the majority of his party was eager to bestow upon him. He unhesitatingly decided to "bolt," and on the evening of the adjournment of the Convention, at a meeting in Orchestra Hall, he advised the formation of a Progressive party. A later Convention of the Roosevelt men throughout the country, including a considerable number of Democrats, nominated Roosevelt, with Gov. Hiram W. Johnson of California for vice-president. Meanwhile the Democrats had nominated Woodrow Wilson, governor of New Jersey. The result was a three-cornered political contest, in which it was clear at the beginning that Taft could not be elected, but that Roosevelt probably could not win enough Democratic votes to prevent the choice of Wilson. Nevertheless, Roosevelt fought vigorously through the campaign, violently attacking Taft as a reactionary and tool of reactionaries. While on a speaking tour at Milwaukee he was shot by a fanatic, but was not seriously injured.

The result of the election was the choice of Wilson, who had 6,000,000 popular votes and 435 electoral votes; Roosevelt, 4,000,000 popular votes, and 88 electoral; Taft, 3,500,000 popular votes, and 8 electoral. On this showing the Progressives had more votes than their Republican adversaries, and therefore hoped to compel a reconstruction of the party. Their Republican opponents, however, kept tight hold of the name, organization and prestige. They had deliberately accepted defeat in advance in order to put Roosevelt out of the running.

This, the first serious defeat that Roosevelt had ever encountered, was to him a bitter humiliation. He felt that his public career was ended. His first movement was characteristic. He had cordial invitations to visit S. America and make addresses in the principal cities. As in his experiences of 1910, this dovetailed in with a plan of exploration. Accordingly, early in 1913, after visiting several S. American countries, including Brazil and Argentina, he returned to Brazil, made his way overland, and came down a river, whose uncharted course he followed for 600 miles. The hardships were severe, and he received an injury, serious for a time, and drew into his system the seeds of tropical malaria. The Brazilian Government named the stream Rio Teodoro.

On his return to the United States, out of office, a defeated candidate, an insurgent, the personal enemy of the Republican leaders, he seemed justified in his belief that his career was over. But as usual his enemies played into his hands. An obscure journalist ventured publicly to accuse him of drunkenness. In May 1913 he instituted a suit for defamation of character, with the result that the defendant broke down and acknowledged his error. A large section of the American people resented the affront, and rejoiced in the vindication. During this period Roosevelt was indefatigable as journalist and writer, first in *The Outlook*, then in the *Metropolitan* magazine, and finally through the columns of the *Kansas City Star*.

The outbreak of the World War gave him a new opportunity for his pen and voice. His instinct was against Germany as an oppressor of weak nations; but he stayed his desire for positive action for a time, from the feeling that he ought not to embarrass the President. It was at this time that a personal enemy gave Roosevelt the opportunity of again showing his character to his countrymen, through a publicity which both Roosevelt and the public enjoyed. William Barnes, one of the acknowledged leaders of the Republican party, brought a suit in April 1915 against Roosevelt because of an accusation of unfair and corrupt politics as a "boss" which Roosevelt had made against him. Roosevelt vigorously defended himself and won the suit. For 10 days he was on the witness-stand, and his testimony, which was spread broadcast throughout the land, revealed his undiminished force and appealed to the popular imagination.

The sinking of the "Lusitania" by a German submarine in May 1915 brought his bitterest denunciation, and from that time he foresaw first the possibility and then the likelihood of war between Germany and the United States. He made himself the leading spokesman for "preparedness," and presently drew down the wrath of President Wilson's administration for a speech at Plattsburg. From that time he did not spare sharp criticisms of President Wilson's policy as showing unwillingness to face the dangers of war. His utterances against Germany and in favour of the Allies had great influence.

As the election of 1916 drew near, the remaining Progressives, aided by some who had stayed in the Republican party, made an effort to force the Republican Convention to nominate Roosevelt. They called a Progressive Convention to meet at Chicago at the same time as the Republican, hoping to make a joint nomination with the Republicans. Roosevelt did his best to secure the prize, but again the party leaders would have none of him. Hughes was nominated, and this time Roosevelt accepted the situation as a loyal member of the Republican party, and supported the nominee.

As the World War went on, Roosevelt became the severest critic of the administration and the strongest advocate of preparedness. He formed a plan for raising a special division, in which he hoped to have a command, and which he would offer to the Government. Early in 1917, when the American breach with Germany came, he offered the services of himself and his sons, all four of whom subsequently enlisted. He requested that he might have a personal command, which was denied by the administration, although both Houses of Congress united in a bill making his plan possible. During the year he made some of the most notable addresses of his life, especially that before the "Order of Moose" Convention in Pittsburgh. By this time the Republican politicians were looking forward to the election of 1920 and began to group themselves about Roosevelt. His most persistent enemies, even William Barnes, accepted his nomination as a foregone conclusion. The year 1918, however, was a sad one for Roosevelt. His son Quentin was killed in the war. Ever since returning from Brazil, Roosevelt's constitution had shown weakness. He was several times in hospitals, and underwent a serious operation for abscess due to infection received during his Brazilian explorations. The hearing of his left ear was wholly destroyed. Still he continued his writing and speaking, and his direct personal influence upon his thousands of friends. Even in the first days of 1919, when he suffered from renewed disease, he looked forward to public service. On Jan. 6 1919 he died in his sleep.

A man who could do so much could not do everything perfectly, though few have ever done so many things so well. It was more true of him than of most men that his defects were inherent in his virtues. There were few half-tones in Roosevelt's moral perceptions and fewer in his vocabulary; he saw things as either black or white, and he forgot sometimes that he had not previously seen them as he saw them at the moment. He had enemies, and even former friends, who charged him with breaking promises, betraying political associates and setting his own wishes and interests above all others. The very intensity of his convictions sometimes blinded him to the sincer-

ity and even to the justice of other points of view. Nevertheless this intensity, this moral fervour, gave his ideas a momentum and a success which they could never have acquired had they proceeded from a more judicial mind. He scorned "weasel words," and on occasion he did not hesitate to describe his enemies as thieves and liars. His remarkable energy reminded observers of some great elemental force which, like any natural phenomenon, is controlled by its own necessary laws. When Lord Morley was leaving the United States in 1904 he was asked by reporters what in America had impressed him most. "Two things," he replied, "Theodore Roosevelt and Niagara Rapids."

His fearlessness was as conspicuous as his energy. With a courage very rare in political life he attacked the iniquities that had crept into the conduct of American business. He asserted the importance of personal rights when these were being openly denied in the name of property rights. He rallied the patriotic elements of the country against the menace of a private "money power" which not only had frequently dictated the course of legislation but threatened to usurp the authority of the Government itself. He felt strongly that any position involving the exercise of power had its obligations as well as its privileges, and this feeling lent force to his denunciation of "predatory interests" and "malefactors of great wealth." On the other hand he had little patience with demagogic attacks on men or corporations merely because they were rich or successful, as was shown in his famous utterance in which he compared the authors of these journalistic attacks with the "muckrakers" in *Pilgrim's Progress*. It was said of him satirically that he had invented the Ten Commandments; but Roosevelt's earnestness in behalf of old truths was of the essence of his service to his countrymen, and more important at the juncture than the discovery of new ones.

His great personal power was used in the furtherance of honesty, fair dealing and patriotic service, when more than lip service to these virtues was vitally needed. He threw all his energy into the effort to bring about a reapplication of fundamental moral principles to American business and political life. While he was unquestionably an astute politician, the secret of his success lay in his imaginative understanding of the views and feelings of his countrymen: his enthusiasm was contagious because he vividly expressed what they already felt and believed to be the truest American ideals. When he spoke for the "square deal," the American people as a people always responded.

Born of a wealthy family, in an aristocratic society, enjoying all his days a literary and artistic atmosphere, he was still a natural democrat. He had a personal interest in every man or woman that he met, and a genuine affection literally for thousands of individual persons. He was a scientific man whose observations and deductions were valued by naturalists and investigators. He was a literary man, very widely read. He was an intellectual man, interested from youth to age in literature and philosophy. He was a politician without a rival in his time for boldness, foresight, and an innate knowledge of what his fellow countrymen were thinking about. He was a statesman of the most brilliant ability, who after a crushing defeat returned to power over the minds of the people and was on his way again to the presidency of the United States. His bitterest political enemies accepted his coming back to national leadership. To few men in history has it been given to wield such far-reaching and wholesome personal influence.

BIBLIOGRAPHY.—Between 1909 and 1919 Roosevelt published about 15 books, several of them consisting of articles and addresses. The more important are *African Game Trails* (1910); *Conservation of Womankind and Children* (1912); *Theodore Roosevelt, an Autobiography* (1913, contains little beyond 1909); *Life-Histories of African Game Animals* (2 vols. 1914); *A Hunter-Naturalist in the Brazilian Wilderness* (1914); *Through the Brazilian Wilderness* (1914); *A Book-lover's Holiday in the Open* (1916). His principal later books on public affairs and on the World War are *Realizable Ideals* (1912); *America and the World War* (1915 and 1919); *Fear God and Take Your Own Part* (1916); *National Strength and International Duty* (1917); *The Great Adventure* (1918). Numerous collections of extracts and speeches have been published, especially those of W. F. Johnson (1909); L. F. Abbott (African and European, 1910); W. Griffith (1919); J. B. Bishop, *Letters to his Children* (1919).

The most important biographies are those by J. B. Bishop (1920); H. Hagedorn, *Boy's Life of Theodore Roosevelt* (1919); W. D. Lewis (1919); W. R. Thayer (1919); Bradley Gilman (1921) and H. Hagedorn's *Roosevelt in the Bad Lands* (1921). A useful list of books by and about Roosevelt is J. H. Wheelock's, *Bibliography of Theodore Roosevelt* (1920). (A. B. H.)

ROOT, ELIHU (1845-), American lawyer and political leader (see 23.711), was elected president of the N.Y. State Bar Association in 1910, and chairman of the board of trustees of the Carnegie Institution of Washington in 1913. He was chairman of the N.Y. State Republican Convention in 1912, 1913, 1914, 1916, and permanent chairman of the Republican National Convention in 1912. In 1913 he favoured the repeal of the bill exempting American shipping from Panama Canal tolls. He also approved President Wilson's policy of non-interference in Mexico. He assailed as class legislation the exemption of labour unions and agricultural associations from the Sherman Anti-Trust Act. On Dec. 10 1910 he was awarded the Nobel peace prize because of his work in the pacification of the Philippines and Cuba as well as his part in the negotiations between the United States and Japan. The same day he became a member of the Court of Arbitration for settling the claims of British, French and Spanish subjects in connexion with property seized by the Portuguese Government when a republic had been proclaimed. In 1915 he opposed Secretary Bryan's treaty with Colombia, disapproving any apology for incidents attending the acquisition of the Canal Zone and regarding the proposed payment of \$25,000,000 as too large. He attacked the Ship Purchase bill, pointing out dangers of international difficulties in case interned vessels were taken over. He also argued that for the Government to acquire shipping would discourage private enterprise and was socialistic in tendency. He was president of the State Constitutional Convention in 1915 and worked for many reforms, including the short ballot, means for remedying the law's delays and the excessive cost of securing justice, and the making of impeachments easier. When submitted to the voters, however, the new constitution was defeated. He was unanimously elected president of the American Bar Association in 1915. The same year he retired from the U.S. Senate, having refused to stand for a reelection.

He had long advocated preparedness on the part of the United States and early in 1917 spoke in favour of war against Germany. After the United States entered the World War he urged full support of the President. In May 1917 he was appointed chairman of the special American mission sent to Russia and was given the rank of ambassador. Arriving at Petrograd in June he addressed the Russian Council of Ministers and in Moscow spoke at a special session of the Duma and at a meeting of the local Council of Workmen's and Soldiers' Delegates. Later he visited General Brusilov at staff headquarters. On his return to America he was elected honorary president of the National Security League, succeeding Joseph H. Choate. On Sept. 25 1917 he presided at the meeting of the National Association Opposed to Woman Suffrage and denounced suffrage agitation during the critical period of the war. He had never supported the movement and in 1914 had been blacklisted by the National American Suffrage Association. He approved in general the Covenant of the League of Nations but in 1919 suggested six amendments to protect American interests, including reservations concerning the Monroe Doctrine and immigration. He favoured separate consideration of the Peace Treaty and the League. He was strongly opposed to the Prohibition amendment to the Federal Constitution; was retained as counsel by several brewing interests and in 1920 argued before the U.S. Supreme Court against its constitutionality, but unsuccessfully. In 1920 the President reappointed him U.S. delegate to the Hague Tribunal and he went to Holland to assist in organizing the Permanent Court. In July 1920 he spoke at the unveiling of St. Gaudens' statue of Lincoln in London. In 1921 he was one of the four U.S. delegates at the Washington Conference on the Limitation of Armament.

He was the author of several volumes of lectures and addresses, including *Experiments in Government and the Essentials of the Con-*

stitution (1913, lectures delivered at Princeton); *Addresses on International Subjects* (1916); *Addresses on Government and Citizenship* (1916); *The Military and Colonial Policy of the United States* (1916); *Latin America and the United States* (1917); *Miscellaneous Addresses* (1917); *North Atlantic Coast Fisheries at The Hague* (1917) and *The United States and the War* (1918).

ROSCOE, SIR HENRY ENFIELD (1833–1915), English chemist (see 23.725), died at Leatherhead, Surrey, Dec. 18 1915.

ROSEBURY, ARCHIBALD PHILIP PRIMROSE, 5TH EARL OF (1847–), British statesman (see 23.731), took an active part in the constitutional crisis in 1910 and 1911. He treated the Parliament bill as a revolutionary measure which in effect constituted single-chamber Government, and did his utmost to arouse the nation to a sense of its danger. But he disapproved of the bill which Lord Lansdowne introduced in May 1911 for the reconstitution of the House of Lords, holding that the Opposition ought to have contented themselves with reaffirming his own resolutions of the previous year. If the Parliament bill became law, Lord Lansdowne's bill mattered little; who would then be the acolytes and sycophants who would accept the degrading position of members of a second chamber? While, however, he bitterly condemned the conduct of ministers in going to "a young and inexperienced King" for contingent guarantees, he declined to follow the extreme course of rejecting the bill recommended by the "Die-hards." He shrank from the scandal of a great creation of peers. If the bill were allowed to pass, the House would be left with some vitality; if the creation of peers was forced, they would have none at all. He showed his own estimate of the impotence of the House after the passage of the bill by ceasing to attend its debates; and indeed he took no further part in public life till the outbreak of war in 1914 fired his patriotism. As lord-lieutenant of Midlothian and Linlithgowshire he promoted recruiting and other warlike activities in his own country; and helped to hearten the nation and to avert a premature peace by occasional speeches. His feeling was shown by a preface which he wrote in Oct. 1914 for the first volume of Col. John Buchan's *History of the War*. He spoke of "the incalculable blessing which the damnable invasion of Belgium has conferred incidentally upon ourselves. . . . It has revealed to the world the enthusiastic and weather-proof unity of the Empire. . . . Blood shed in common is the cement of nations, and we and our sons may look to see a beneficence of empire, not such as the Prussians dreamed of, not a war-lordship over other nations, not a nightmare of oppression, but a world-wide British influence which shall be a guarantee of liberty and peace, and which, hand-in-hand with our Allies in Europe and with our kindred in the United States, should go far to make such another war as this impossible."

The war cost Lord Rosebery his younger son, the Right Hon. NEIL PRIMROSE (1882–1917), whose political advance had been watched by his father with eager sympathy. He was under-secretary for the Foreign Office in 1915, parliamentary secretary for Munitions in 1916, and at the close of that year became Coalition Liberal Whip under Mr. Lloyd George. But these appointments were only held for short periods in the intervals of fighting as a captain in the Buckinghamshire Hussars, and he died of wounds received in action in Palestine in Nov. 1917. He had married Lord Derby's daughter in 1915. Lord Rosebery had a further domestic sorrow in the dissolution, in 1919, of the marriage (celebrated in 1909) of his elder son Lord Dalmeny with Dorothy A. M. A. Grosvenor. Lord Rosebery was created Earl of Midlothian in the peerage of the United Kingdom—the earldom of Rosebery being a Scottish earldom—at the coronation of King George in 1911, at which ceremony, as at the coronation of King Edward, he was one of the lords who bore the canopy. He became chancellor of Glasgow University in 1908 as he had long been chancellor of London University; and was chosen lord rector of St. Andrews University for the year of its quincentenary celebration in 1911.

ROSEGGER, PETER (1843–1918), Austrian poet and novelist (see 23.734), died in 1918. (See AUSTRIAN EMPIRE: Literature.)

ROSENTHAL, TOBY EDWARD (1848–1917), American painter (see 23.735), died in Berlin, Germany, Dec. 28 1917.

ROSENWALD, JULIUS (1862–), American merchant and philanthropist, was born at Springfield, Ill., Aug. 12 1862, and was educated in the public schools. From 1885 to 1906 he was president of Rosenwald & Weil, clothing manufacturers, Chicago. In 1895 he became vice-president and treasurer of the mail-order house of Sears, Roebuck & Co., Chicago, and in 1910 president. The gross sales of the company, which were \$1,750,000 in 1896, increased under his management to \$258,000,000 in 1919. He served during the World War under appointment by President Wilson as a member of the Advisory Commission of the Council of National Defense. In 1918 he was sent on a special mission of cheer by Secretary Baker, of the War Department, to the American troops in France. In 1919–20 he served in Washington as a member of the President's Industrial Conference. He devoted much time to work for philanthropic, educational and civic organizations. He gave \$150,000 to Tuskegee (Ala.) Normal and Industrial Institute; \$250,000 for a building to house Jewish philanthropic organizations of Chicago; and (with Mrs. Rosenwald) \$750,000 for new buildings for the university of Chicago. Of the latter sum \$250,000 was used to erect a building, Julius Rosenwald Hall, for the departments of geology and geography, and \$500,000 for buildings for the medical department. He founded dental infirmaries in the Chicago public schools. During the World War he gave large sums to relief organizations, in 1917 alone \$1,000,000 to aid sufferers in eastern Europe. He contributed generously to, and took a leading part in securing contributions for, the Hoover Children's Relief Fund in 1920–1. Beginning in 1914, he stimulated a programme for building rural schools for negroes in the southern states by agreeing to contribute toward their cost and toward the lengthening of the school terms, provided both the whites and the negroes of the neighbourhood contributed also and that public funds were appropriated. Up to 1920, 800 schools were thus constructed at a total cost of \$1,500,000, of which Mr. Rosenwald gave \$400,000. In 1920, 500 additional buildings were authorized for immediate construction at an approximate cost of \$2,000,000, of which Mr. Rosenwald agreed to pay \$500,000. At the close of 1920, 14 cities had Y.M.C.A. buildings for negroes, costing altogether \$2,000,000, because of Mr. Rosenwald's offer to contribute \$25,000 to each city under certain conditions. His share in the cost was \$350,000. He was an official of several leading philanthropic, civic and educational organizations of Chicago, including the university of Chicago; also of the Rockefeller Foundation, Tuskegee Normal and Industrial Institute, the Baron de Hirsch Fund and the American Jewish Committee, and was identified with many other movements for public benefit throughout the country.

On Dec. 29 1921 it was announced that Mr. Rosenwald had pledged about \$20,000,000 to safeguard the interests of Sears, Roebuck & Co. during the critical period of business readjustment after the World War. He increased the company's fluid assets by purchasing for \$16,000,000 part of the real estate owned by the company in Chicago, and gave the company from his own holdings 50,000 shares of its common stock (par value \$100). In 1920 and 1921 the company had paid no dividends on its common stock and it was apparent that its accounts at the end of 1921 must show a deficit. But Mr. Rosenwald by this action enabled the company to readjust its finances without impairing its capital stock, and protected its stockholders, many of them employees. It was recognized generally that he established a precedent which raised the standards of business when he thus faced heavy loss in order to protect those who had bought shares because of their confidence in his leadership, and also in order to foster the practice of employees' participative investment.

ROSS, SIR GEORGE WILLIAM (1841–1914), Canadian politician (see 23.739), was knighted in 1910. He published, amongst other works, *The Life and Times of the Hon. Alex. Mackenzie* and *Getting into Parliament and After*. He died March 8 1914.

ROSS, ROBERT BALDWIN (1869–1918), British art critic and writer, was born at Tours May 25 1869, the son of the

Hon. John Ross, Q.C., attorney-general for Upper Canada, his mother being a daughter of the Hon. Robert Baldwin, premier of Upper Canada. He was educated privately, and later at King's College, Cambridge. After leaving the university he took to journalism. As a judge of pictures he was in very high repute, and from 1912 to 1914 he acted as adviser to the Board of Inland Revenue on picture valuations for estate duty. The most noteworthy feature of many years of his life, however, was his friendship with Oscar Wilde, whose literary executor he ultimately became. He was responsible for the publication of Wilde's *De Profundis* (1905), and subsequently for a complete edition of Wilde's works. Not long before his death Ross received from his admirers a presentation of plate, and also a sum of money which, at his request, was applied to the foundation of a scholarship at the Slade school of art. He died in London Oct. 5 1918.

ROSS, SIR RONALD (1857–), British physician and bacteriologist, was born at Almora, India, May 13 1857. He studied medicine at St. Bartholomew's hospital, and in 1881 entered the Indian medical service. About 1893 he commenced a series of special investigations on the subject of malaria, and by 1895 had arrived at his theory that the micro-organisms of this disease are spread by mosquitos (see 17.463, 20.786). In 1899 he retired from the Indian medical service, and devoted himself to research and teaching, joining the Liverpool school of tropical medicine as lecturer, and subsequently becoming professor of tropical medicine at Liverpool University. In 1913 he became physician for tropical diseases to King's College, London. During the World War Ross was appointed to the R.A.M.C. and became War Office consultant in malaria. In 1902 he received the Nobel prize for medicine, in 1911 a K.C.B., and in 1918 a K.C.M.G. He has also been the recipient of honours from many British and foreign universities. He published in 1910 *The Prevention of Malaria*, and also produced *Psychologies*, a volume of poems (1919), and a romance, *The Revels of Orsera* (1920).

ROSTAND, EDMOND (1869–1920), French dramatist (see 23.754), devoted himself during the World War chiefly to the writing of patriotic verse. Various comic versions of *Cyrano de Bergerac* were performed by the soldiers at the front, one of which, *Cyrano de Bergerac aux Tranchées* (1916), was prefaced by Rostand with some of his own verses. He died in Paris Dec. 2 1920. His two sons, Maurice and Jean, have produced various works, the former having published a volume of poems, *Le Page de la Vie* and *Le Cercoeur de Cristal*, and the latter an important pamphlet on wealth.

ROSYTH (see 14.718).—The development of the German navy in the first years of the 20th century rendered it necessary to create a British naval base suitable for a fleet concentrated in the North Sea, and in 1903 it was decided to establish a first-class naval base at Rosyth on the Firth of Forth. Land was acquired and works were planned, but the development of possibilities of torpedo attack soon made it evident that the outer anchorage, as originally designed, would be insecure, and naval opinion became doubtful as to whether the base would be adequate. The plans of construction were, therefore, modified in 1908, but, up to the outbreak of war, Rosyth was regarded as the principal base and headquarters for the Grand Fleet, though it was decided that initial stations must be established at Cromarty (see CROMARTY) and Scapa Flow (see SCAPA FLOW). When the war began, Admiral Jellicoe preferred to establish his headquarters at Scapa Flow, but Rosyth was used as a secondary base, particularly for the battle cruisers.

The Firth of Forth had been selected, before the war, as the eastern terminus of a mid-Scotland canal which was to connect with the existing canal and follow its line for part of the way, and then crossing the low ground in the neighbourhood of Stirling, to enter Loch Lomond, and ultimately to reach the sea by a short canal from Balloch to a point near Dumbarton. The canal was projected not only for commercial purposes but also to enable warships to pass safely and rapidly from W. to E. and to make the great Clyde shipyards easily accessible from the naval base at Rosyth, and thus to avoid the necessity of constructing docks and repairing yards there. The project was again under consideration during the war, but it was obvious that it could not be accomplished in time, and Rosyth was developed as a great dock-yard.

The original scheme included a high-level main basin covering an area of 55 ac., with an entrance lock from the fairway, a dry or graving dock 750 ft. long and 110 ft. wide, a submarine tidal basin, the construction of an entrance channel, and the erection of workshops and offices, and work was begun in 1909. The whole site of the works has been reclaimed from the sea, and a great sea-wall was built to form the southern boundary of the docks, the number of which was increased from one to three. Great progress had been made by the outbreak of war, and it was anticipated that the works would be completed by the summer of 1916. Operations were pushed on vigorously during the war, and a special Act of Parliament was passed in 1915 to facilitate the provision of dwelling-houses for Admiralty employees. By the original Act for the construction of the base, the whole area between the town of Dunfermline and the land purchased by the Government was brought within the municipal area, which was thus extended from 2,016 to 7,730 acres. The erection of houses has involved the construction of new roads, and new water and sewerage schemes.

ROTHENSTEIN, WILLIAM (1872–), English artist, was born at Bradford, Yorks, Jan. 29 1872, and was educated at the Bradford grammar school. In 1888 he entered the Slade school, studying under Legros, and afterwards worked in Paris. In 1893 he began exhibiting at the New English Art Club. His paintings include "The Browning Readers" (1900), "The Doll's House" (1900), "Aliens at Prayer" (1904), "Jews Mourning" (1905), "Carrying the Law" (1910), "Morning at Benares" (1911), "Bourlon Church" (1919), and "The Last Phase: on the Rhine" (1919). Among his portraits may be mentioned those of Augustus John, Sir Francis Darwin (1905), Mr. Charles Booth (1908), Prof. Alfred Marshall (1908), Mr. Bernhard Berenson (1910), and Sir Rabindranath Tagore (1912); besides a portrait of himself (1900), now in the Metropolitan Museum, New York. His work is represented in many galleries, including the Dublin Gallery of Modern Art, the National Gallery, Melbourne, the National Portrait Gallery, Edinburgh, and the galleries of Bradford, Manchester and Johannesburg. He was in 1917 elected professor of civic art at the university of Sheffield. His published works include *Oxford Characters* (1896); *English Portraits* (1898); *The French Set, and Portraits of Verlaine* (1898); *Manchester Portraits* (1899); *Liber Juniorum* (1899); a *Life of Goya* (1900); *Plea for a Wider Use of Artists and Craftsmen* (1918); *Twenty-four Portraits* (1920).

His brother, ALBERT DANIEL RUTHERSTON (b. 1881), who took the name of Rutherford in place of that of Rothenstein in 1916, was born at Bradford Dec. 5 1881. He studied at the Slade school in 1898, and after 1901 exhibited regularly at the New English Art Club. He became well known as a theatrical designer of great taste and originality, his work including designs for *The Winter's Tale* (1912); G. B. Shaw's *Androcles and the Lion* (1913) and *Le Mariage Forcé* (1913). He also illustrated *The Children's Blue Bird* by Madame Maeterlinck (1913).

ROTHERMERE, HAROLD SIDNEY HARMSWORTH, 1st Visct. (1868–), British newspaper proprietor and financier, was the second son of Alfred Harmsworth, and brother of Visct. Northcliffe (see NORTHCLIFFE). He was born April 26 1868 at Hampstead, London, was created a baronet in 1910, Baron Rothermere in 1914, and Visct. Rothermere of Hemsted after his services as Air Minister, in 1918. He married in 1893 Mary Lilian, daughter of George Wade Shaw. At the age of 21 he entered the publishing firm in which his brother Alfred (afterwards Lord Northcliffe) was then the principal, soon after the date when *Answers* was launched. He assisted in developing the business on sound and economic lines, and for the next 20 years he was the close associate of his brother in all his great undertakings and shared in his triumphs. His administrative and financial skill admirably seconded Lord Northcliffe in working out his original schemes. He took an important part in the reorganization of the London *Evening News*, when his business talent helped to make that once insolvent newspaper a large profit-yielder. He was one of the three principals in the establishment of the *Daily Mail* (1896), for many years controlled the finance of that newspaper, and was largely responsible for developing its methods of distribution. He was equally active at the Amalgamated Press, the gigantic periodical publishing

business which his brother had founded after the success of *Answers*. He founded the *Glasgow Daily Record*, bought the *Leeds Mercury*, and shared in the purchase of *The Times* (1908). He became known also as a most generous benefactor of charities. By the gift of a large sum he enabled the Union Jack Club to provide worthy accommodation for sailors and soldiers in London; and he gave £10,000 to the Territorial Force County of London Association. In 1910 he founded the King Edward chair of English literature at Cambridge, and in the same year he ceased his connexion with *The Times*, *Daily Mail*, and *Evening News*. In 1914 he acquired the *Daily Mirror* from Lord Northcliffe, and this henceforth became his special organ. In 1915 he founded the *Sunday Pictorial*, the first fully illustrated Sunday newspaper in London.

In the World War, Mr. Lloyd George, while Secretary for War, appointed Lord Rothermere in 1916 Director-General of the Royal Army Clothing Department. In the following year he accepted the office of Air Minister, under Mr. Lloyd George as Premier. He at once declared himself "whole-heartedly in favour of reprisals," which were the best means of carrying the war into Germany and protecting British towns against air attacks. Suffering from precarious health and his bereavements in the war, he resigned on April 25 1918, after he had carried out the fusion of the Royal Naval Air Force and Royal Flying Corps. "My second tragic loss in the war, ten weeks since," he wrote to the Prime Minister, "caused me great distress of mind and body . . . I was suffering from ill-health and insomnia." Immediately after the war he began a most energetic campaign against extravagance in national and local finance, himself contributing numerous articles to his newspapers.

The tragic losses to which he referred were those of his two sons, Capt. Harold Alfred Vyvyan St. George Harmsworth, M.C. (b. Aug. 2 1894) and Lieut. Vere Sidney Tudor Harmsworth (b. Sept. 25 1895), both of whom, after showing exceptional promise in civil fields, served with extreme gallantry in battle and fell in the national cause. Harold, in the Irish Guards, was twice severely wounded in 1915, and was then given a staff appointment in England. This he insisted on resigning and returned to his battalion at the front. There in Bourlon Wood, on Nov. 27 1917, he received mortal wounds of which he died on Feb. 12 1918. In recording the grant of the M.C. for his conduct on that occasion the *London Gazette* stated: "He led his company forward under heavy fire and himself put out of action two enemy machine-guns. It was entirely due to his splendid example that his company reached their objective." In his memory Lord Rothermere founded and endowed the Harold Vyvyan chair of American history at Oxford University in June 1920. Vere, educated for the navy which he had to leave owing to gun-deafness, joined the Royal Naval Division immediately after the outbreak of war, took part in the expedition to Antwerp, and, when his battalion was driven across the frontier into Holland, made his escape from Dutch internment. He was in the terrific fighting at Gallipoli and in the battle of the Somme, having refused a staff appointment, like his brother, because he was determined to share the fortunes of his men. Twice wounded in the storming of Beaumont on Nov. 13 1916, but still advancing and setting an example which, as his commander wrote, "thrilled with pride the men of his battalion," he was struck a third time by a shell and killed. In memory of him Lord Rothermere in 1919 established and endowed the chair of naval history at Cambridge which bears his name.

Lord Rothermere's third and only surviving son, Esmond Cecil (b. May 26 1898), who had served during the last part of the war in the Royal Marine Artillery, was in 1919 elected "anti-waste" M.P. for Thanet, and was then the youngest member of the House of Commons and the fifth of his family in Parliament. (H. W. W.)

ROTHSCHILD, NATHANIEL MAYER, 1ST BARON (1840-1915), Jewish financier, was born in London Nov. 8 1840, the son of Lionel Nathan de Rothschild, Austrian baron, head of the English branch of the famous financial family (see 23.758). He was educated at Trinity College, Cambridge, and in 1879

succeeded his father as Austrian baron. He sat in the House of Commons from 1865 to 1885 when he was created a peer by Mr. Gladstone, the first of his race and religion to be raised to the House of Lords. He was well known as an agriculturist as well as a financier, and he was renowned for his charities. He died in London March 31 1915.

His brother, **LEOPOLD DE ROTHSCCHILD** (1845-1917), who had been throughout associated with him in the management of the financial house, succeeded him as its head and also took over most of his public offices, besides interesting himself especially in the Jewish community and becoming president of the United Synagogue. He was an art collector and owner of race-horses. He died at Ascott, Leighton Buzzard, May 29 1917.

ROUND, JOHN HORACE (1854-), English historian, only son of John Round, lord of the manor of West Bergholt in Essex, and through his mother grandson of Horace Smith, author of *Rejected Addresses*, was born at Brighton on Feb. 22 1854. He was educated privately, afterwards going to Balliol College, Oxford, where he took a first-class in modern history. The teaching of Dr. Stubbs, then Regius Professor of History, greatly stimulated the young student, whose independent and critical genius had already begun to revolt against the superficial methods of historical study traditional in the English schools, and after a few years he devoted himself to historical research. His own aim as a historian, as stated by himself, was "to add to or correct our knowledge of facts" (preface to *Feudal England*), and from the first he insisted that students of mediaeval history must go to the records in order to find evidence to supplement and check the chroniclers on whom historians of the type of Freeman had too exclusively relied. In 1883 he published in the *Antiquary* a criticism of Brewer's introduction to the *Book of Hoveth* (Rolls Series), in which he proved that the author was "strangely at fault" in his views on its authorship, its origin and its contents; and three years later, in his *Early Life of Anne Boleyn*, he again pointed out errors "on the simplest matters of fact" made by the same eminent scholar. In 1884-5 he published in a magazine articles on "The Origins of the House of Lords" (reprinted in *Peerage and Pedigree*, 1910), in which he argued for "that feudal origin of the House which, in view of the teaching of Freeman and Stubbs, it was, at that time, heresy to assert." In 1888 appeared his edition of *Ancient Charters, Royal and Private, prior to 1200* (Pipe Roll Soc. vol. x.), in the preface to which he pointed out their use for genealogy, topography, legal and ecclesiastical antiquities, etc. In 1891 appeared his *Introduction to Knight-service into England* (privately printed, reprinted in *Feudal England*, 1895), in which he proved the entirely Norman and feudal origin of this institution (see the article by Round in the *E.B.* 15.867).

In 1892 he published in the *Quarterly Review* (vol. 175, No. 349) his famous attack on Freeman's historical method. He accused him of working as a historian "not from manuscripts, but from printed books," and pointed out "the danger to our national school of history in the wide-spread and almost superstitious belief in his unimpeachable authority." This authority he proceeded to assail, centring his attack on that "palisade" of solid timber which, in his *Norman Conquest*, Freeman had imaginatively built round the English host at "Senlac," and proving that this palisade had as little existence as "Senlac" itself (see *E.B.* 13.59 note). Round had begun openly to attack Freeman as early as 1882, but the fact that the *Quarterly* article, though written before Freeman's death, did not appear till afterwards excited unjust comment, and blinded the dead historian's friends to the convincing force of the criticism itself. The long and bitter controversy that followed was summed up by Round in "Mr. Freeman and the Battle of Hastings" in *Feudal England*. In 1892 also appeared *Geoffrey de Mandeville*, a study of the anarchy under Stephen, which established the author's reputation as a constructive historian. In *Feudal England*, which appeared in 1895, Round published in collected form some of the results of his researches into the history of the 11th and 12th centuries, the first part of the book setting forth views as revolutionary on the Domesday side and the whole system of land

assessment as on the actual introduction of the feudal system into England. In 1899 was published his *Calendar of Documents preserved in France illustrative of the history of Great Britain and Ireland*, vol. i., pp. 918-1206, and also another collected series of studies under the title of *The Communes of London*. In the following year he published his *Studies in Peerage and Family History*, and at the Congress of Archaeological Studies he read a paper (subsequently published) on "the systematic study of our English place-names," in which he again pointed out the impossibility of accomplishing any scientific work in the department of research until the place-names of England had been classified and traced to their origins.

Round's vast and detailed knowledge of the periods which he had made his own led to his opinion being sought by successive law officers of the Crown charged with the conduct of peerage cases brought before the House of Lords. His attention was thus drawn to peerage law, and he soon discovered that there "was room for its treatment on fresh and historical lines." In 1910 he published *Peerage and Pedigree*, containing studies on peerage law and its problems, in which incidentally he attacked "the muddle of the law," pointing out that the lawyer, whose vision is bounded by his "books," is still in the Middle Ages, while the historian is a man of science. Although the labour involved in these peerage cases was immense, Round refused to accept any remuneration; in 1912, however, his services were publicly recognized by the creation in his favour of the new office of Honorary Adviser to the Crown in Peerage Cases. His passion for historic truth led him to wage ruthless war on the "pedigree-mongers," whom he attacked with mordant wit (see, e.g. in *Peerage and Pedigree*, "Some 'Saxon' Houses," "The Great Carington Imposture"), and on those who were attempting to give a false value to the possession of coats-of-arms (*ibid.* "Heraldry and the Gent"). Occasionally he extended the range of his attacks, falling, for instance, upon those who, consciously or unconsciously, falsified history in the interests of particular political or religious opinions (e.g. "The Elizabethan Religion, in correction of Mr. George Russell," *Nineteenth Century*, vol. xli., p. 191).

History on a large scale Round never attempted. His books are all collections of particular studies, and they represent but a tithe of his published work. He edited, with prefaces, a whole series of the Pipe Rolls; he was a frequent contributor to the *English Historical Review*; he helped to edit the *Ancestor*, for which he also wrote; and innumerable papers by him are scattered in various historical and archaeological journals and reviews. In 1913 he had begun to prepare a catalogue of these scattered works, but in 1921 this had not yet been published. Round's historical method—reaching conclusions by induction from isolated facts whose connexion he had in turn to prove—prevented his becoming a popular writer; but his style is always luminously clear, and the articles contributed by him to this *Encyclopædia* (DOMESDAY, KNIGHT SERVICE, BARON, BARONET, EARL, BAYEUX TAPESTRY, SCUTACE, the families of FITZGERALD and NEVILLE, etc.) are excellent examples of his capacity for concise statement. (W. A. P.)

ROUVIER, MAURICE (1842-1912), French statesman (see 23.781), died at Reuilly-sur-Seine June 7 1912.

ROVNO, BATTLE OF.—The Rovno operations played an important part in the Russian campaign of 1915 on the eastern front (see EASTERN EUROPEAN FRONT CAMPAIGNS).

In consideration of Austro-Hungarian troops having been set free by the rally of Mackensen's group of armies in their victorious march on Brest Litovsk, and of the connexion between the Russian N.W. and S.W. fronts having been broken by the withdrawal of the former N. of the Polesie, the Austro-Hungarian army Higher Command decided, on Aug. 27 1915, to take the offensive with the army front which had been inactive on the Zlota Lipa and the Bug. The objects in view were Rovno (Rowne) and the liberation of the east portion of East Galicia.

The S. wing of the II. Army under Böhm-Ermolli, and the N. wing of the Southern Army under Bothmer, made a successful attempt to break through Shtcherbachev's XI. Army in the

battle at Gologory and on the Zlota Lipa. Bothmer's S. wing and the N. wing of the VII. Army engaged Lechitski's IX. Army; Puhallo advanced with the main body of the I. Army towards the bent back N. wing of Brussilov's VIII. Army to throw it back on Dubno; and Field-Marshal Roth-Limanowa pushed forward on the Kovel (Kowel)-Luck road in order to capture from the Russians the command of the northern flank. Puhallo's advance decided Ivanov to break off the battles and to withdraw Brussilov during the night, and Shtcherbachev and Lechitski's N. wing on the 28th and 29th to a position behind the Sierna, on the watershed between the Bug and the Styr, on the Zloczów heights and behind the Strypa. The S. wing and centre of the Austro-Hungarian front followed immediately in pursuit, and in consequence two battles developed, after the occupation of the Russian position: one, on the 30th on the Strypa, from whose bridgeheads Shtcherbachev and Lechitski delivered mighty blows against Bothmer's S. wing and Pflanzer-Baltin's N. wing; the other, on the 29th at Zloczów, where Böhm-Ermolli attempted to break through.

Puhallo only arrived before Brussilov's front on the 29th and had to put off attacking until the 31st. Roth, having encountered opposition at Rozyszcze on the 29th, had advanced with the main body across the Styr at Sokul, and that day began a forced march towards Luck. The XXXIX. Corps, brought up by train, flung itself upon him but was defeated on the 30th.

Ivanov made Brussilov withdraw in the night behind the Putilowka and go into position at Olyka, Mlynów, Kozin and the source of the Ikwa. Luck was surrendered. Shtcherbachev held the Zloczów heights until the morning of Sept. 1, although he was surrounded on the N. and his front was broken through in places. He then retired to the position Radziwillów-Podkamien-Zalozce.

Lechitski was still holding out on the 1st, in spite of the failure of his counter-assaults, and Pflanzer-Baltin therefore delivered an assault with his group, established N. of the Dniester close to the mouth of the Sereth. During the night the Russians fell back on to the strongly fortified Sereth position, which was provided with several bridgeheads.

Ivanov hoped that his N. wing, which had been bent back a long way and was difficult to envelop owing to the adjacent marsh area, and had, further, been reinforced by fortress artillery from Rovno, would be able with the aid of flank attacks from the region of dense forests and impassable swamps known as Polesie ("the Woods") to hold out until the S. wing, opposed by far weaker forces, should have lifted the whole front off its hinges by a victorious assault.

The Austro-Hungarian army Higher Command arranged for the N. wing, now divided into two armies under Archduke Joseph Ferdinand, to deliver a decisive blow by means of assaults on Rovno and Dubno; for Böhm-Ermolli to break through in the centre of the Russian front; and for Bothmer and Pflanzer-Baltin to contain the Russian forces by an attack on the Sereth position. Lechitski wanted to employ the time until his N. and Shtcherbachev's S. wing should be ready, by removing the threat to his flank offered by Pflanzer-Baltin's troops, who had advanced on both sides of the Lower Sereth. These battles on the 4th and 5th, combined with a simultaneous attack on the Bukovina, failed in their object.

While Bothmer was grouping his army for a break-through S. of Tarnopol, and Pflanzer-Baltin's N. wing was waiting to attack simultaneously with him on the 7th, the Russians, on the afternoon of the 6th, opened the battle of the Sereth (the battle of Tarnopol) with a great mass assault from the Trembowla area. On the same day Böhm-Ermolli finished the battle at Podkamien, begun on the 2nd, with a victory that resulted in Shtcherbachev's N. wing retiring as far as Butyn on the Goryn, while Brussilov's S. wing, abandoning Dubno, fell back behind the Middle Ikwa.

Archduke Joseph Ferdinand's I. and IV. Armies, which had come up in front of the Russian positions on the 2nd, defended themselves against numerous counter-assaults, by which Brussilov was trying to prevent the diversion of troops to the N.

wing. The pressure on the flank from Polyesie grew, and it became imperative to bring up all cavalry divisions within reach. These became entangled in difficult minor combats in the midst of forest and marsh. On Sept. 8 Archduke Joseph Ferdinand delivered at Cuman the blow which decided the battle of Olyka. Brussilov escaped by retreating behind the Stubla.

These successes barred the advance of the Sereth front, which by 7 P.M. had forced back Bothmer's and Pflanzer-Baltin's inner wings as far as the Strypa. Böhm-Ermolli's S. wing executed a relief attack E. of the Sereth towards Zbaraz. Ivanov, in his anxiety for his N. wing, ordered the S. wing reserve to be diverted and sent to its relief. This wing was for the moment endeavouring to cover the flanks of the attack-group which had advanced a great distance, but could overpower neither Bothmer's N. wing in the direction of Tarnopol nor the troops in the foreground of the Zaleszczyki bridgehead. On the 10th the Archduke Joseph Ferdinand began the battle of the Stubla, which he hoped to bring to a decision by sending the N. wing to cross the Goryn below the mouth of the Stubla, and then make an advance on Rovno simultaneously with that of Puhallo's army coming from Dubno. By the 12th the road to the Goryn had been made clear, one division brought across the river, and the groups which threatened the N. wing driven back a considerable distance.

The arrival of Russian reinforcements opposite to Böhm-Ermolli's sparsely occupied front, as well as the arming for a continuation of the Sereth front's advance, showed that Ivanov was planning a great offensive on both sides of the Tarnopol-Lemberg line. The Austro-Hungarian army Higher Command stopped Puhallo's advance, drew back Bothmer's N. wing to the level of the Strypa front and dispatched thither the VI. Corps which had been intended for use against Serbia.

On the 13th the counter-offensive set in with the battle of Krzemieniec-Gontowa, and won some initial successes. The N. wing's attack was now also stopped. On the 14th the Russians broke through the Strypa front and reached the W. bank. The VI. Corp's attack, together with an advance by Bothmer's N. wing and a group of Böhm-Ermolli's posted W. of the Sereth on the N. flank, caused the Russians to retire again in the night of the 16th-17th to their Sereth position. During this time Böhm-Ermolli had repulsed the assault, and used the reinforcements sent by the Archduke for an attack. But a calamity had overtaken the N. wing. Keeping the attention of the weakened group of armies on the Stubla cleverly riveted, Brussilov with the XXX. Corps on the 15th threw back the N. wing behind the Putilowka and forced the Archduke, by continuous envelopment, to retreat behind the Styr and the Ikwa on the evening of the 17th. The bridgehead at Luck could not hold out, and on the 23rd the Russians stood on the E. bank of the river. On the same day Shtcherbachev and Brussilov's S. wing advanced to the attack on the II. Army and Puhallo's I. Army, now under command of Böhm-Ermolli, from the Upper Sereth to the mouth of the Ikwa. This second battle of Krzemieniec ended on the 25th with the failure of the Russians. At the same time Brussilov received the news that German troops had taken part in the storming of the bridgehead at Kolki on the Styr. Recognizing the intentions of the allies, he at once ordered a retreat to the Putilowka position, while concentrating a powerful group to the N. of the Kormin brook to fall on the enemy's flank.

Linsingen, the new commander of the IV. Army and of the troops in Polyesie, was in fact planning a blow on the Russian flank and rear by way of Kolki-Sokol, using for this purpose the German XXIV. Reserve Corps (brought up from the German front through Polyesie after Gyllenschmidt's forced retreat behind the Wiszoiucha and the Styr) and the Austro-Hungarian XVII. Corps which was to have been sent against Serbia. Gerok's group, the XXIV. Reserve and the XVII. Corps, had now to do with nothing but rearguards, who by the 27th had been overthrown. On the 28th, when Shtcherbachev at the battle of Nowo Aleksinieć again attacked Böhm-Ermolli in order to keep his forces engaged, the main body of the N. wing arrived at the Putilowka. Linsingen guessed Brussilov's scheme,

made Gerok wheel to the N.E., and intercepted the Russian blow. The allies' decision to grant the much-exhausted troops some rest in a permanent position brought the battle of the Putilowka to an end on the evening of the 30th.

The Russian command refused to be satisfied with this close to a campaign which had not brought them much gratification. On Oct. 3 Gyllenschmidt delivered a flank blow from Rafalowka, W. of the Styr, but was driven completely back by the 6th. This attack against Serbia was a spur to renewed exertions. On the 6th a fresh battle set in on the Putilowka, which on the 7th spread over the whole front up to the Rumanian frontier, lasting until the 10th—until the 13th on the Strypa—without a change in the situation. On the 15th Ivanov once more delivered a blow on the N. flank in the bend of the Styr at Czartorysk, which at first made great progress. But Linsingen's clever concentric placing of the hurriedly brought-up reinforcements drove the Russians back with heavy fighting behind the Styr by Nov. 14. During the crisis Shtcherbachev had attacked the II. Army in vain from Oct. 21 to 23 in the second battle of Nowo Aleksinieć. More dangerous still were the Russian attempts to break through on the Strypa from Oct. 30 to Nov. 8, which culminated in the struggle for the village of Siemikowce. Finally in the middle of Nov. a prolonged lull fell upon this theatre of war. (M. H.)

ROWELL, NEWTON WESLEY (1867—), Canadian politician, was born Nov. 1 1867 in Middlesex county, Ontario. He was called to the bar in 1891, and became head of the law firm of Rowell, Reid, Wood & Wright, Toronto; ultimately being made bencher of the Law Society of Upper Canada in 1911. He stood unsuccessfully as a Liberal for the Dominion Parliament at the general election of 1900, but in 1911 was elected to the Ontario Legislative Assembly for N. Oxford. From 1912-7 he was leader of the Liberal Opposition in the Ontario Legislature. On Oct. 1917 he entered the Federal Unionist Government as president of the council and vice-chairman of the War Committee of the Cabinet, and was elected to the Dominion House of Commons for Durham county, Ontario, Dec. 1917. He was a member of the Imperial War Cabinet and Imperial War Conference, 1918; Canadian Government representative at the International Labour Conference at Washington, 1919; and a Canadian delegate to the first assembly of the League of Nations at Geneva, 1920. He resigned his seat in Parliament in May 1921.

ROWING: see SPORTS AND GAMES.

ROYCE, JOSIAH (1855-1916), American philosopher, was born at Grass Valley, Cal., Nov. 20 1855. He graduated from the university of California in 1875 and the following year went to the newly established Johns Hopkins University, being one of the extraordinary first group of fellows elected there. After receiving his Ph.D. in 1878 he was instructor in English literature and logic for four years at the university of California. In 1881 he prepared *A Primer of Logical Analysis* for students of English composition. In 1882 he was called to Harvard where he taught as instructor in philosophy, assistant professor (1885-92), professor of the history of philosophy (1892-1914) and Alford professor of religion, moral philosophy, and civil polity (after 1914). He was the leading American exponent of idealism (see 14.284) and his works were distinguished for their literary qualities. He was made a member of the National Institute of Arts and Letters, and received hon. degrees from Harvard, Yale, Johns Hopkins, Aberdeen, St. Andrews and Oxford. After the outbreak of the World War he was a staunch supporter of the Allies, and on Jan. 30 1916, in a notable address delivered in Tremont Temple, Boston, advocated a breach with Germany. He died in Cambridge, Mass., Sept. 14 1916.

He was the author of *The Religious Aspects of Philosophy* (1885); *California* (1886, in the American Commonwealth Series); *The Feud of Oakfield Creek* (1887, a novel); *The Spirit of Modern Philosophy* (1892); *The Conception of God* (1895); *Studies of Good and Evil* (1898); *The World and the Individual* (2 vols., 1900-1; Gifford Lectures at the university of Aberdeen); *The Conception of Immortality* (1900); *Outlines of Psychology* (1903); *Herbert Spencer: An Estimate and Review* (1904); *The Philosophy of Loyalty* (1908); *Race Questions, Provincialism and Other American Problems* (1908).

William James and Other Essays on the Philosophy of Life (1911); *Brass Lectures on the Sources of Religious Insight* (1912); *The Problem of Christianity* (2 vols., 1913, lectures before Manchester College, Oxford); *War and Insurance* (1914); *The Hope of the Great Community* (1916, war addresses) and the posthumously published *Lectures on Modern Idealism* (1919).

ROYDEN, AGNES MAUDE (1876–), English social worker and preacher, was born at Mossley Hill, Liverpool, Nov. 23 1876, the daughter of Sir Thomas Royden, 1st Bart., of Frankby Hall, Birkenhead. She was educated at Cheltenham Ladies' College and Lady Margaret Hall, Oxford, and afterwards for some years did settlement work in Liverpool. She also lectured on English literature for the university extension movement, and in 1909 was elected to the executive committee of the N.U.W.S.S. From 1912 to 1914 she edited the *Common Cause*, the organ of the union. Miss Royden became well known as a speaker on social and religious subjects, and in 1917 became assistant preacher at the City Temple, being thus the first woman to occupy this office.

RUBBER (see 23,795*).—Since 1910 the rubber industry has developed very largely and taken increased importance in the commercial world. The word rubber is applied to three different substances: (a) an elastic solid, the chief constituent of the coagulated latex or milk of a great variety of trees, shrubs, vines and plants, as Para rubber; (b) an elastic solid found in solution in the tissues of a few shrubs and vines, as Guayule rubber; (c) a chemical product from isoprene or homologous hydrocarbons, as synthetic rubber. In all commercial rubber caoutchouc exists in two forms, one fibrous or hard, the other viscous and soft. In the best trades the fibrous form preponderates. The soft form can be dissolved by benzol and many other substances of that class; the fibrous form swells but does not dissolve. Vulcanization (the chemical union of caoutchouc and sulphur) hardens the viscous portion. As the result of this process the rubber becomes less sensitive to heat and cold and to the effect of acids and alkalis and becomes more durable. A small amount of sulphur in rubber produces soft rubber. By using more sulphur and greater heat a very hard black substance called hard rubber is obtained. Moulding India rubber consists of softening by heat the stiff rubber dough until it is plastic, pressing it into a mould and vulcanizing it at a heat much less than that required to melt it; not in melting, pouring and casting according to popular misconception. Rubber once melted remains a sticky, worthless semi-fluid.

Wild Rubber.—At first there were but three types of rubber to be found in the world's markets: India rubber, the product of the *Ficus elastica* from Assam, Burma and Java; gum elastic,

the product of the *Hevea brasiliensis* from S. America, and "virgin gum" from the *Castilloa elastica* of Central America. In 1921 all grades from whatever source were termed India rubber, and there were some 200 sorts. They were divided generally as follows: (1) S. American rubber, from the *Hevea brasiliensis* and kindred species which comprised Para rubber in 3 general grades and 20 sub-grades; Caerá rubber (Manicoba) from the *Manihot glaziovii* and kindred species, 6 grades; Mangabeira from the *Hancornia speciosa*, 2 grades; and Caucho rubber from the *Castilloa ulei*, 3 grades. (2) Central American rubber, known as "centrals," the product of *Castilloa elastica* and kindred species, some 25 grades; virgin rubber, the product of the *Sapium tolimense* and kindred species, 3 grades; Guayule rubber, from the *Parthenium argentatum*, 12 grades. (3) African rubber, a lower grade of wild rubber, produced by a great variety of vines of the *Landolphia* genus and to a degree from trees, as the *Ficus vogelii* and the *Funtumia elastica*. The number of grades was 120. (4) E. Indian rubber, the product chiefly of the *Ficus elastica* from Rangoon, Penang and Java, 9 grades; together with Borneo rubber from the *Willoughbia firma*, 3 grades; Pontianak (Jelutong), from the *Dyera costulata*, 4 grades. (5) Plantation rubber. From 1860 attempts to cultivate rubber-bearing trees and vines have been undertaken in various parts of the tropical world. The most persistent and finally the most successful were carried on in the British experiment stations and Royal botanic gardens, especially in Ceylon and the Straits Settlements. A measure of success was attained in cultivating the *Manihot glaziovii*, the *Castilloa elastica*, the *Ficus elastica* and the *Funtumia elastica*. All of them proved to be good rubber-producers but could be tapped only at intervals of several months. The product found ready sale, and considerable plantations of *Manihot* in Ceylon, and *Ficus* and *Castilloa* in the Federated Malay States were installed. American interests also planted thousands of acres of *Castilloa* in Mexico, Nicaragua and Guatemala. Experiments with another tree, however, the *Hevea brasiliensis*, developed the fact that through what was termed "wound response" it could be tapped daily without injury. This process in brief was the opening of the tapping cut by the removal daily of a thin shaving of the bark. The amount from each tapping was small, but the year's product far exceeded that of the planted trees of any other sort. The result was that most of the others were abandoned or destroyed and the *Hevea brasiliensis* put in wherever it could possibly thrive. Thus the *Hevea* plantation product, which in 1900 was four tons, increased to 8,400 tons in 1920, and from then on the increase was very large, as shown in the table below.

Hevea Plantation Acreage and Production.

	Plantation Acreage	Plantation Production (tons)	Total Wild Rubber Production (tons)	Total World's Production (tons)
1910	1,122,550	8,200	62,300	70,500
1911	1,505,350	14,419	60,730	75,149
1912	1,817,350	28,518	70,410	98,928
1913	2,021,750	47,618	60,822	108,440
1914	2,181,050	71,000	49,000	120,380

Approximate World Consumption of Rubber, 1920.

United States	260,000 tons
Great Britain and Colonies	50,000 "
France	20,000 "
Italy	10,000 "
Japan	8,000 "
Other Countries	16,000 "
Total	364,000 tons

Synthetic Rubber.—From the time when India rubber began to be important in the arts, its synthetic production was the dream of the inventor. Analysis of rubber with a view to ultimate synthesis was made between 1835 and 1840 by Dalton, Liebig, Himly, A. Bouchardat and Gregory. A more systematic attempt to isolate and examine the products in crude caoutchouc distillate was made in 1860 by Greville Williams, the English chemist. He obtained isoprene, C_4H_8 , a hemiterpene, a fluid boiling at $37^\circ C.$, and a hydrocarbon now known as dipentene, boiling at 170 to $173^\circ C.$, which he named "heveene." An important step towards the production of artificial rubber was that taken by Gustave Bouchardat of the Paris School of Pharmacy in 1879, when, in studying the action of hydrochloric acid on isoprene, he noted the formation of a substance having the same percentage composition as isoprene, lacking chlorine, possessing elasticity, insoluble in alcohol but soluble in ether and carbon bisulphide like natural rubber, and yielding on distillation the same hydrocarbon as caoutchouc. Sir William Tilden, the English chemist, in 1882 observed the polymerization of isoprene and that it could be converted into true caoutchouc with certain chemical reagents. In 1884 he obtained isoprene by passing the vapours of turpentine through a hot tube. In 1887 Prof. Otto Wallach of the university of Göttingen noted that isoprene undergoes polymerization on exposure to light with the production of a rubber-like mass, and Tilden in 1892 showed that such material could be vulcanized with sulphur. The synthesis of isoprene and, as a consequence, that of caoutchouc, was accomplished; in 1897 by Prof. Euler-Chelpin of the university of Stockholm. In 1909, due to the rapidly mounting cost of natural rubber, greater efforts were made to produce the artificial kind on a commercial scale, the problem being attacked in England by W. H. Perkin, his assistant Weizmann, and Francis Matthews; by August Fernbach in France; and in Germany by the Bayer and Badische companies. In 1884 Tilden suggested that not only isoprene but its homologues should be capable of similar polymerization. Now these bodies, chief among them butadiene, form the basis of methods for obtaining synthetic caoutchoucs. Dr. Fritz Hofmann and Dr. Carl Coutele, chemists in Germany, in 1909 devised a process for making absolutely pure isoprene, converted it into rubber by heating it in a closed tube or in the presence of other substances, and sent the sample to Prof. C. D. Harries, of Kiel University, who pronounced it true rubber. In 1910 Prof. Harries showed that isoprene could be converted into rubber by heating it in a closed tube with glacial acetic acid. He had in 1905 determined the chemical constitution of natural rubber. The German scientists did not confine themselves to isoprene but experimented successfully with the homologous hydrocarbons suggested by Tilden. Harries and the English investigators, Matthews and E. Halford Strange, noted independently that polymerization proceeds at great velocity in the presence of metallic sodium and the resulting rubber differs much in its properties from that produced by mere heating. German chemists observed different results when polymerization by sodium was carried on in an atmosphere of carbonic acid. A later process in Germany was based on the use of ozonizers on sodium hydrogen peroxide as catalysers. Some of the synthetic rubbers are soluble, elastic, and may be readily vulcanized; others possess only some of these qualities. They are obtained from butanes, dimethylbutanes, and from isoprene, and in each of the three classes are to be found standard ozonide, carbonic acid and sodium rubbers.

Despite this wide range of materials with their possible use in the arts, the making of synthetic rubber is still a minor industry as com-

pared with the production of natural rubber and the manufacture of goods therefrom. In the manufacture of the hydrocarbons of the isoprene series for synthetic rubber there are such large quantities of by-products that their removal or utilization presents a problem more difficult than the production of the artificial rubber; hence competition with natural rubber is very unlikely. Synthetic rubbers lack the durability of natural rubber, possibly because they lack the resins, albumen, etc., which act as protective colloids to lessen the vulnerability of the natural article. Then, too, for a wide range of needs, synthetic rubbers cannot be substituted for natural rubber because the latter product is a uniform vegetable substance, not a mixture like the artificial product. While synthetic rubber must be greeted as a chemical triumph, it is not an industrial success, and must still be classed commercially with the more or less haphazard production of alleged rubber substitutes prepared, often by honest inventors and manufacturers, from oils, gums, cellulose, or in fact anything that will produce a waterproof plastic.

Reclaimed Rubber.—In few other industries is conservation such an important factor as in rubber manufacture. Nearly all kinds of worn-out vulcanized goods are collected and the basic material recovered to be compounded, manufactured and vulcanized again into new articles that compare favourably with those made from new gum. To so many uses is devulcanized or reclaimed rubber now put, that its annual consumption fully equals that of new crude gum. Experiments early demonstrated the value of "reclaim," and while the more conservative long looked askance at the utilization of "refuse rubber," buyers of goods made wholly or in part from the regenerated material found that for most purposes the goods were practically as serviceable as those made directly from fresh gum. The element of cost, too, played an important part in popularizing reclaimed rubber, as articles made of it could be produced and sold for much less than those made with new gum only, and to a considerable degree the price of the crude gum has been kept from rising too high by the ample supply of the reclaimed. As the advantages of reclaimed rubber became better appreciated, and as through the activities of rubber chemists and manufacturers the quality of the product was improved, it became an important factor in the industry. To meet more satisfactorily the fast-growing demand, large companies with world-wide connexions and specialized equipment soon supplanted the small reclaimers. Such concerns employ not only the most modern machinery but also maintain research and analytic laboratories for control of the processes, for standardizing the products, and for the study of reclaiming and compounding problems.

The first attempt to reclaim rubber commercially was that made in the early 'fifties when Hiram L. Hall, the pioneer manufacturer in Massachusetts, boiled powdered vulcanized rubber in water and then sheeted it. Francis Baehnel, an early American experimenter, next patented a method for devulcanizing rubber, finely ground, by exposing it to live steam. An important later development was the destruction of fibre in the ground material by means of acids, chiefly sulphuric, for which processes over 50 patents were granted, which incidentally became the subject of much litigation. The acid process was of use chiefly in the reclaiming of worn-out footwear or "dry heat" goods, but was not of great value in recovering other waste. The alkali process, patented by Arthur Hudson Marks, an American manufacturer, solved the latter problem. In this, caustic soda was used to destroy the fabric and incidentally it proved to be the most effective agent in desulphurizing the mass. The entire removal of not only the free sulphur from vulcanized rubber (which modern reclaiming accomplishes) but also of the sulphur which during curing unites chemically with the crude rubber, is the goal towards which experimenters were striving in 1921. Notable progress in this direction had been made in England by Dr. David Spence, who used an accelerator, aniline-potassium, but in solution in excess of aniline. He claimed not only the dissolution of the waste rubber but the liberation in soft rubber of from 78% to 90% of the combined sulphur, and the changing of the latter into an insoluble alkaline sulphide. In hard rubber 73% of the combined sulphur was said to be similarly reduced.

Vulcanization, or curing, is effected generally by either the heat cure or the cold cure. In the first-named method either steam or heated air is employed. A wide range of rubber goods, either in moulds wrapped with strips of cloth, or imbedded in pans of French talc to preserve their shape, is very efficiently cured with live steam in various types of vulcanizers. For many other needs the dry-heat cure, in which the goods are placed in a hot compartment without either wrapping or mould protection, has

been found serviceable. Still another heat cure, now but little used, is that of solarization, whereby the fabrics, coated with a thin skin of rubber, are exposed to the sun's rays for vulcanization. In very exacting work, such as the vulcanizing of hard-rubber sheets, curing is effected by immersion of the material in hot water. In the cold cure either the acid or the vapour process is employed. In the former, goods are dipped in solution of chloride of sulphur dissolved in bisulphide of carbon, after which they are given an alkali wash. For the vapour cure, rubber goods are suspended in a heated compartment in which the fumes of chloride of sulphur pass freely over the surfaces to be vulcanized. Over-curing is checked by the admission of ammonia fumes.

Since Charles Goodyear (see 12,240) in 1839 discovered, and in 1844 patented, his process for vulcanizing rubber with sulphur by means of heat, numerous attempts have been made radically to improve on his method and material; but the bulk of the rubber goods produced is still cured by the sulphur and heat method. In the long train of experiments, many of which have led to important results, the curing of rubber has been effected by the use of sulphates, sulphides, chlorides, nitrates, fluorides, bromides, iodides and phosphores of nearly all the common earths and metals, as well as chlorine, sulphurous acid and various gases. The Russian chemist Ivan Ostro-mislensky, in later experiments, succeeded in vulcanizing rubber with trinitrobenzene and other nitro-compounds so as to impart all the qualities given it by sulphur, effecting the curing more rapidly than with sulphur, and with but one-twelfth of the material, while a lower temperature was maintained during the cure. Victor Henry, a French chemist, also reported in 1909-10 that he had effected the vulcanization of thin layers of rubber solutions by means of the ultra-violet rays, and others have made similar researches along the same line that have much scientific if not practical interest. The period of vulcanizing ranges from a few minutes to many hours, depending on the degree of heat employed, the nature of the compound, the thickness of the goods, etc. Factors which affect the rate of cure, as shown in England by Dr. Philip Schidrowitz, are the amount of protein or nitrogen in the crude gum, its stay in storage, its density, the amount of smoke, formalin or other preservatives used, quantity of acid used in coagulating the latex, time in drying, age of latex-yielding tree, etc. An important vulcanization development is the chemical process of vulcanization described by S. J. Peachey, the English chemist, in 1918, after an investigation of the behaviour of rubber towards the various allotropic forms of sulphur. Unlike the Parkes process, which yields an addition-product of both sulphur and chlorine, this leads to the formation without the aid of heat of a sulphur addition equal to that produced by the hot-curing process. By it rubber, alone or compounded with fillers and pigments, is exposed successively to the action of two gases, sulphur dioxide and hydrogen sulphide. Diffusing through the rubber and interacting, the gases produce an especially active form of sulphur capable of combining with and vulcanizing the rubber at the ordinary temperature, and more thoroughly than by either the hot process or the sulphur-chloride cure. A density is acquired, it is said, unattainable by the older methods. The dual gas treatment can be used either for rubber in its original solid form or liquefied with a solvent. In the latter case the gases effect a complete pectization of the solution, forming a jelly which, on evaporating the solvent, is found to be fully vulcanized rubber. One of the advantages claimed is that fabrics, as well as organic fillers such as leather waste, sawdust, woodmeal, etc., that would be more or less decomposed by the hot cure or the sulphur-chloride cure, could be used with rubber for a wide variety of new and useful purposes, as in the making of fine or heavy reformed leathers, linoleums, etc. It may also effect a considerable improvement in the waterproofing of cloth. Rubber footwear, it is said, may be produced by the new process without either the heat or pressure hitherto deemed essential, and without special machines for stitching and riveting, thus greatly cheapening the product. An additional advantage pointed out is that this process makes it possible to use both natural and coal-tar colouring-matter in rubber, so as to obtain both deep shades and delicate tints impossible with the old methods of vulcanizing.

Organic Accelerators in Vulcanization.—The recent discoveries of Dr. Spence and others that certain organic substances, termed accelerators or catalysers, mixed with rubber, notably hastened the process of vulcanization, have caused a revolution in compounding and vulcanizing. Mineral or inorganic catalysers, such as litharge and magnesia, had been in use since the discovery of vulcanization. The organic type was, however, unknown until in attempts to vulcanize synthetic rubber it was found necessary to add organic accelerators to effect the union of the synthetic rubber-like substance. It was but a short time before the connexion with natural rubber, and the relation of the two, was established. In fact, the time required in vulcaniza-
